Abstract. This paper is concerned with the state-constrained optimal control of the two-dimensional thermistor problem, a quasi-linear coupled system of a parabolic and elliptic PDE with mixed boundary conditions. This system models the heating of a conducting material by means of direct current. Existence, uniqueness and continuity for the state system are derived by employing maximal elliptic and parabolic regularity. By similar arguments the linearized state system is discussed, while the adjoint system involving measures is investigated using a duality argument. These results allow to derive first-order necessary conditions for the optimal control problem.

1. Introduction. In this paper we consider state-constrained optimal control of the two-dimensional thermistor problem. In detail the optimal control problem under consideration looks as follows:

\[
\begin{align*}
\text{minimize} & \quad J(\theta, u) := \frac{1}{2} \int_D |\theta(T) - \theta_d|^2 \, dx + \frac{\beta}{2} \int_{\Sigma_N} u^2 \, ds \, dt \\
\text{subject to} & \quad (1.1) - (1.7) \\
& \quad \text{and} \quad \theta(x, t) \leq \theta_{\text{max}}(x, t) \quad \text{a.e. in } Q \\
& \quad 0 \leq u(x, t) \leq u_{\text{max}}(x, t) \quad \text{a.e. on } \Sigma_N
\end{align*}
\]

where (1.1)–(1.7) refer to the following coupled PDE system consisting of the instationary heat equation and the quasi-static potential equation, which is also known as thermistor problem:

\[
\begin{align*}
\partial_t \theta - \text{div}(\kappa \nabla \theta) &= (\sigma(\theta) \nabla \varphi) \cdot \nabla \varphi & \text{in } Q := \Omega \times [0, T[ \\
\nu \cdot \kappa \nabla \theta + \alpha \theta &= \alpha \theta_l & \text{on } \Sigma := \partial \Omega \times [0, T[ \\
\theta(0) &= \theta_0 & \text{in } \Omega \\
- \text{div}(\sigma(\theta) \nabla \varphi) &= 0 & \text{in } Q \\
\nu \cdot \sigma(\theta) \nabla \varphi &= u & \text{on } \Sigma_N := \Gamma_N \times [0, T[ \\
\varphi &= 0 & \text{on } \Sigma_D := \Gamma_D \times [0, T[ \\
\nu \cdot \sigma(\theta) \nabla \varphi &= 0 & \text{on } (\partial \Omega \setminus \Gamma_N \cup \Gamma_D) \times [0, T[ (1.7)
\end{align*}
\]

Here \( \theta \) is the temperature in a conducting material covered by the two dimensional domain \( \Omega \), while \( \varphi \) refers to the electric potential. The boundary of \( \Omega \) is denoted by \( \partial \Omega \) with unit normal \( \nu \) facing outward of \( \Omega \). In addition, \( \Gamma_D \) is a closed part of \( \partial \Omega \), while \( \Gamma_N \) is an open part of \( \partial \Omega \) which is disjoint to \( \Gamma_D \). Moreover, \( T \) is a given end time, \( Q = \Omega \times [0, T[ \) is the space-time cylinder with boundary \( \Sigma = \partial \Omega \times [0, T[ \), and \( \Sigma_N \) and \( \Sigma_D \) are defined analogously. Furthermore, \( \kappa \) and \( \sigma \) represent heat and electric conductivity. While \( \kappa \) is a given, prescribed function, \( \sigma \) is allowed to depend on the temperature. Moreover, \( \alpha \) is the heat transfer coefficient and \( \theta_l \) and \( \theta_0 \) are given boundary and initial data, respectively. The bounds in the optimization problem (P) as well as the desired temperature \( \theta_d \) are given functions and \( \beta \) is the usual Tikhonov regularization parameter. Finally, \( D \) is an open part of \( \Omega \) and \( u \) denotes the control. The precise assumptions on the data in (P) and (1.1)–(1.7) will be specified in Section 2. In all what follows, the system (1.1)–(1.7) is frequently also called state system.

The PDE system (1.1)–(1.7) models the heating of a conducting material by means of a direct current induced on the part \( \Gamma_N \) of the boundary. At the anode \( \Gamma_D \), homogeneous Dirichlet boundary conditions are given, whereas one has insulation on \( \partial \Omega \setminus \Gamma_N \cup \Gamma_D \). We point out that the different boundary conditions are essential for a realistic modeling of the process. The objective of (P) is to adjust the induced current \( u \) to minimize the \( L^2 \)-distance between the desired and the induced temperature at end time \( T \). Moreover, the optimization is subject to pointwise control and state
constraints. The control constraints reflect a maximum heating power, while the state constraints limit the temperature evolution to prevent possible damage, e.g. by melting of the material. Similarly to the mixed boundary conditions, the inequality constraints in (P) are essential for a realistic model as demonstrated by the numerical example within this paper. Problem (P) underlies various applications, such as for instance the heat treatment of steel by means of an electric current. The example, considered in the numerical part of this paper, will deal with an application of this type.

The state system (1.1)–(1.7) exhibits some non-standard features, in particular due to the quasi-linear coupling of the parabolic and the elliptic PDE, the mixed boundary conditions in (1.5)–(1.7), and the inhomogeneity in the heat equation (1.1). A slightly different version of the thermistor problem is discussed by Chipot et al. (see [3] and the references therein). The system considered in [3] differs from (1.1)–(1.7) since it accounts for temperature dependent heat conductivities, but does not allow for mixed boundary conditions and non-smooth domains. The discussion of the state system (1.1)–(1.7) heavily rests on maximum elliptic and parabolic regularity results as derived in Gröger [16, 17]. Based on these results, it is possible to prove continuity of the temperature as solution of (1.1)–(1.7), which is essential in the presence of pointwise state constraints as the inequality constraints on \( \theta \) in (P). In particular, the application of Gröger’s results implies the restriction to two dimensional domains since comparable results for the three dimensional case are not available.

Up to the authors’ best knowledge, there are only few contributions dealing with the optimal control of the thermistor problem. We refer to [22] and [21], where, similarly to our setting, two dimensional problems are discussed. In [22], a complete parabolic problem is discussed, while [21] considers the purely elliptic counterpart to (1.1)–(1.7). Moreover, both contributions neglect the mixed boundary conditions and do not consider pointwise state constraints and non-smooth data. Thus, (P) differs significantly from the above mentioned papers.

Problem (P) represents a quasi-linearly coupled state-constrained optimal control problem. Such optimization problems are known to provide particular difficulties, especially due to the pointwise state constraints. In the semi-linear case, the analysis of state-constrained optimal control problems is already quite comprehensive. We only mention [4, 7, 25, 6] and the references therein. Concerning the state-constrained optimal control of semi-linear elliptic PDEs with mixed boundary conditions, we refer to the recent publication [19]. In contrast to the semi-linear case, less is known for the control of quasi-linear PDEs. Concerning quasi-linear, elliptic problems with pointwise state constraints, we refer to [8]. Hence, the discussion of optimal control of a quasi-linearly coupled PDE system in the presence of pointwise state-constraints and mixed boundary conditions represents a genuine contribution to the theory. Here we focus on the first-order analysis of (P). The derivation of second-order sufficient conditions in the case of state-constrained boundary control of instationary problems is still an open question, even in the semi-linear case with smooth data.

The paper is organized as follows: After stating the detailed setting and assumptions in Section 2, the state system is discussed in Section 3. The existence of an optimal solution is shown in Section 4, while Section 5 is devoted to the analysis of the linearized state system. In Section 6, the first-order analysis of (P) is developed, beginning with the differentiability of the control-to-state operator in Section 6.1, followed by the discussion of the adjoint system and the derivation of the optimality system in Sections 6.2 and 6.3, respectively. Finally, some numerical examples for a particular application problem covered by (P) are presented in Section 7.
2. Notations and general assumptions. In all what follows, Ω always denotes a domain in \( \mathbb{R}^2 \) and \( \Gamma_D \) is a closed part of its boundary. The space \( C^\alpha(\Omega) \) denotes the space of Hölder continuous functions, while \( H^{s,q}(\Omega) \) (\( s \in [0,1] \)) is the space of Bessel potentials with differential index \( s \) and summability index \( q \) on the set \( \Omega \). (Please notice that \( H^{1,q}(\Omega) \) coincides with the Sobolev space \( W^{1,q}(\Omega) \).) Further, we use the symbol \( H^{s,q}_D(\Omega) \) for the closure of \( \{ \psi|_\Omega : \psi \in C_0^\infty(\mathbb{R}^2), \text{supp } \psi \cap \Gamma_D = \emptyset \} \) in \( H^{s,q}(\Omega) \). The dual of \( H^{s,q}_D(\Omega) \) with respect to the \( L^2(\Omega) \) inner product is denoted by \( H^{-s,q}_D(\Omega) \) with \( \frac{1}{q} + \frac{1}{q'} = 1 \). The dual of \( H^{1,q}(\Omega) \) is denoted by \( H^{-1,q}(\Omega) \). If \( \Omega \) is understood, we abbreviate \( H^{s,q}, H^{s,q}_D \) and \( H^{-1,q} \), respectively. The symbol \( S \subset \mathbb{R} \) always stands for an (open) interval. If \( X \) is a Banach space, its dual is denoted by \( X^* \). Moreover, by \( W^{1,r}(S;X) \), is the set of those elements from \( L^r(S;X) \) whose distributional derivative also belongs to \( L^r(S;X) \). In this spirit, \( \sigma \) always means the distributional derivative with respect to time, see [1, Ch. III.1] or [12, Ch. IV]. Furthermore, \( C^r(S;X) \) denotes the space of \( X \)-valued, Hölder continuous functions on \( S \). For all these spaces, defined on an interval \( S = [0,T] \) the subscript 0 denotes the corresponding subspace of functions which vanish in \( t = 0 \). All function spaces under our consideration are real ones. For two Banach spaces \( X \) and \( Y \) denote the space of linear, bounded operators from \( X \) into \( Y \) by \( B(X,Y) \). The norm in a Banach space \( X \) will be always indicated by \( \| \cdot \|_X \). If \( X, Y \) are Banach spaces which form an interpolation couple, then we denote by \( [X,Y]_{c,r} \) the corresponding complex interpolation space and by \( (X,Y)_{c,r} \) the real interpolation space, see [27]. Finally \( c \) denotes a generic positive constant.

Now we are in the position to state the main assumptions for the quantities in (P). Please notice that, in order to obtain sharp results, here we just mention the assumptions on the quantities in (1.1)–(1.7) that are needed to obtain existence, uniqueness, and continuity of solutions to the state system. For the Fréchet-differentiability of the associated solution operator one has to require more restrictive conditions which are formulated in Assumption 5.1, see Section 5. We start with the conditions on the domain \( \Omega \):

**Assumption 2.1.** The domain \( \Omega \subset \mathbb{R}^2 \) is a bounded Lipschitz domain (see [15]), and \( \Gamma_N \) is an open part of \( \partial \Omega \), whereas \( \Gamma_D \) is a closed part of \( \partial \Omega \). Furthermore \( \Gamma_N \) and \( \Gamma_D \) have positive measure and are disjoint to each other. In addition, the set \( \partial \Omega \setminus \Gamma_D \cap \Gamma_D \) is finite and no connected component of \( \Gamma_D \) consists of a single point. Moreover, \( T < \infty \) is a given end time.

**Remark 2.2.** In [19], it is shown that Assumption 2.1 implies that \( \Omega \cup (\partial \Omega \setminus \Gamma_D) \) is regular in the sense of Gröger (cf. [16]), which will be of major importance for the discussion of the elliptic equation, see Theorem 3.7 below.

**Assumption 2.3.** On the quantities in the state system we impose:

i) The function \( \sigma(x,\theta) : \Omega \times \mathbb{R} \to B(\mathbb{R}^2) \) is bounded and measurable w.r.t. \( x \) for all \( \theta \in \mathbb{R} \) and Lipschitz continuous w.r.t. \( \theta \) for almost all \( x \in \Omega \), i.e.

\[
\| \sigma(x,\bar{\theta}) - \sigma(x,\theta) \|_{B(\mathbb{R}^2)} \leq L_\sigma |\bar{\theta} - \theta| \quad \text{a.e. in } \Omega, \text{ for all } \bar{\theta}, \theta \in \mathbb{R}
\]

with a constant \( L_\sigma > 0 \). Moreover, for all \( \theta \in \mathbb{R} \) and almost all \( x \in \Omega \), \( \sigma(x,\theta) \) is a symmetric matrix. Finally, it satisfies

\[
\inf_{\theta \in \mathbb{R}} \sup_{x \in \Omega} \sum_{i,j=1}^{2} \sigma_{ij}(x,\theta) \xi_i \xi_j \geq \sigma_0 \| \xi \|_{\mathbb{R}^2} \quad \forall \xi \in \mathbb{R}^2
\]

\[
\sup_{\theta \in \mathbb{R}} \| \sigma(x,\theta) \|_{L^\infty(\Omega;B(\mathbb{R}^2))} \leq \sigma_1
\]
Assumption 2.4.

i) The function $\kappa \in L^\infty(\Omega; \mathcal{B}(\mathbb{R}^2))$ is symmetric for a.a. $x \in \Omega$ and satisfies the usual ellipticity condition, i.e.

$$\text{essinf}_{x \in \Omega} \sum_{i,j=1}^{2} \kappa_{ij}(x) \xi_i \xi_j \geq \sigma_0 \| \xi \|_{\mathbb{R}^2} \quad \forall \xi \in \mathbb{R}^2.$$ 

ii) $\theta_1 \in L^\infty([0,T]; L^\infty(\partial \Omega))$

iii) $\theta_0 \in C(\bar{\Omega})$

iv) $\alpha \in L^2(\partial \Omega)$ with $\int_\Omega \alpha^2 d\omega > 0$ and $\alpha(x) \geq 0$ a.e. on $\partial \Omega$

v) $\beta > 0$

Assumption 2.5. The remaining quantities in (P) fulfill:

i) $D$ is an open (not necessary proper) subset of $\Omega$.

ii) $\theta_0 \in L^2(D)$

iii) $\theta_{\text{max}} \in C(\bar{Q})$ with $\theta_0(x) < \theta_{\text{max}}(x,0)$ for all $x \in \Omega$

iv) $u_{\text{max}} \in L^\infty([0,T]; L^2(\Gamma_N))$, $u_{\text{max}}(x,t) \geq 0$ a.e. on $\Sigma_N$

v) $\beta > 0$

Remark 2.5. We point out that the conditions in Assumption 2.1, 2.3, and 2.4 are satisfied in many relevant cases. In particular, allowing for non-smooth domains is important in many applications.

3. Analysis of the nonlinear state system. We start with a precise formulation of the system (1.1)-(1.7) and the corresponding definition of weak solutions to (1.1)-(1.7). To this end, define for any coefficient function $\rho \in L^\infty(\Omega; \mathcal{B}(\mathbb{R}^2))$

$$-\nabla \cdot \rho \nabla : H^{1,2}_D(\Omega) \to H^{-1,2}_D(\Omega)$$

by

$$\langle -\nabla \cdot \rho \nabla w, z \rangle := \int_\Omega \rho \nabla w \cdot \nabla z \, dx; \quad w, z \in H^{1,2}_D(\Omega).$$

The restriction of these operators to the spaces $H^{1,2}_D(q \geq 2)$ will also be denoted by $\nabla \cdot \rho \nabla$. Analogously, we define

$$K : H^{1,2}(\Omega) \to H^{-1,2}_D(\Omega)$$

by

$$\langle Kw, z \rangle := \int_\Omega \kappa \nabla w \cdot \nabla z \, dx + \int_{\partial \Omega} \alpha w z \, d\omega; \quad w, z \in H^{1,2}(\Omega).$$

where (here and in the sequel) $\omega$ is the surface measure on $\partial \Omega$.

Remark 3.1. The function

$$\iota_0 : [0,\infty[ \ni t \mapsto e^{-tK} \theta_0 \in L^\infty(\Omega)$$

is continuous on $[0,\infty[$ and admits the estimate $\| e^{-tK} \theta_0 \|_{L^\infty} \leq \| \theta_0 \|_{L^\infty}$; see Lemma 3.18 below.

Remark 3.2. For $q \in [2,4]$ one has the embedding $H^{1,\varphi}(\Omega) \hookrightarrow L^{2+\varepsilon}(\partial \Omega)$ for an $\varepsilon = \varepsilon(q) > 0$ and $H^{1,2}(\Omega) \hookrightarrow L^m(\partial \Omega)$ for any finite $m$, see [15]. Assume now $q \in L^2(\partial \Omega)$. If one sets $m := \frac{2(2+\varepsilon)}{\varepsilon}$, then there is a constant $c > 0$ such that, for all $v \in H^{1,2}(\Omega)$ and all $\psi \in H^{1,\varphi}(\Omega)$,

$$\left| \int_{\partial \Omega} \varphi v \psi d\omega \right| \leq \| \varphi \|_{L^2(\partial \Omega)} \| v \|_{L^m(\partial \Omega)} \| \psi \|_{L^{2+\varepsilon}(\partial \Omega)}$$

$$\leq c \| \varphi \|_{L^2(\partial \Omega)} \| v \|_{H^{1,2}(\Omega)} \| \psi \|_{H^{1,\varphi}(\Omega)}.$$
Let \( J \)ness for (1.1)–(1.7). The associated fixed point mapping is constructed as follows:

We here apply Banach’s contraction principle to prove existence and uniqueness in a weak sense.

**Definition 3.3.**

Let \( u \) be the solution operator associated to the elliptic equation (3.10) for almost all \( t \in [0, \infty[ \). The estimate (3.6) shows that \( u \) is continuous in the space of solutions to (1.1)–(1.7) in the sense of Definition 3.3.

**Remark 3.4.**

The reader will verify that the boundary conditions imposed on \( \theta \) and \( \varphi \) in (1.2), (1.5), (1.7) are incorporated in this definition in the spirit of [12, Ch. II.2] or [9, Ch. 1.2], for instance.

The main result, we will show in this section, reads as follows:

**Theorem 3.5.**

Suppose that \( u \) is given in \( L^\infty([0, T]; \mathbb{L}^2(\Gamma_N)) \). Then under Assumptions 2.1, 2.3, and 2.4 there holds:

i) There is a solution of (1.1)–(1.7) in the sense of Definition 3.3.

ii) This solution is unique.

iii) There is an index \( q > 0 \) such that for every \( T > 0 \) the function \( \zeta \) even belongs to \( C^0([0, T]; C^0(\Omega)) \).

iv) If \( \theta_0 \in H^{1,q}(\Omega) \) with \( q > \frac{2}{\eta} \), then \( \theta_0 \) takes its values in a Hölder space \( C^0(\Omega) \) and is Hölderian in time when considered as \( C^0(\Omega) \)-valued, what means \( \zeta + \theta_0 \in C^0([0, T]; C^0(\Omega)) \), if \( \eta > 0 \) is sufficiently small.

**Remark 3.6.**

Please notice that the Hölder property of \( \theta \) in case iv) extends to the boundaries, i.e. \( \theta \in C^0([0, T]; C^0(\Omega)) \), and naturally implies continuity of \( \theta \). This is essential for the derivation of first-order necessary conditions for (P), see Section 6.

### 3.1. Proof of Theorem 3.5.

Let us start with a brief sketch of the proof. In contrast to [3], where Schauder’s fixed point theorem is used to analyze the thermistor problem, we here apply Banach’s contraction principle to prove existence and uniqueness for (1.1)–(1.7). The associated fixed point mapping is constructed as follows: Let \( J : \theta \mapsto \varphi \) be the solution operator associated to the elliptic equation (3.10) for...
given \( u \), while \( K : f \mapsto \theta \) is the solution operator of the parabolic equation (3.9) with right hand side \( f \) (the precise definitions of \( J \) and \( K \) with their domains and ranges, respectively, will be given later on, see Lemma 3.9, 3.11, and 3.21). Then a solution of (1.1)–(1.7) in the sense of Definition 3.3 is equivalent to a fixed point of the equation

\[
\theta = K(\sigma(\bar{\theta})|\nabla J(\bar{\theta})|^2 + \bar{\alpha}).
\]

(3.11)

To prove contractivity of this combined mapping, we apply maximal elliptic and parabolic regularity results in the spirit of Gröger [16] and [17]. These results in particular allow to account for the mixed boundary conditions in the elliptic equation. The contractivity will be first shown on sufficiently small time intervals. A repetition argument then implies the assertion of Theorem 3.5 on the whole time interval.

The proof is organized as follows: we start with the discussion of the elliptic equation. Afterwards the parabolic equation is investigated starting with a summary of some well known results on semigroup theory and maximum parabolic regularity which are proven in Appendix A. Finally the fixed point mapping is constructed and the fixed point assertion follows from Theorem 3.7 and Remark 3.8.

i) The mapping \( J \) which assigns to any function \( \zeta \in L^{\infty}(S; L^{\infty}(\Omega)) \) the function \( t \mapsto \varphi_t \) with \( \varphi_t \) given by

\[
-\nabla \cdot \sigma(\zeta(t) + \nu \theta(t))\nabla \varphi_t = \bar{u}(t)
\]

(3.12)

takes its image in a ball \( B \) in \( L^{\infty}(S; H^{1,q}_D(\Omega)) \) the radius of which only depends on \( \|u\|_{L^\infty(S; L^3(\Gamma_N))} \) (not on \( \theta_0 \in L^{\infty}(\Omega) \) and the interval \( S \)).

ii) \( J : L^{\infty}(S; L^{\infty}(\Omega)) \to B \) is Lipschitz continuous.

Proof:

i) First of all, Remark 3.1 shows that \( \nu \theta_0 \) has globally in time the \( L^{\infty}(\Omega) \)-bound \( \|\theta_0\|_{L^{\infty}(\Omega)} \). Moreover, for almost all \( t \in S \), \( u(t) \in L^2(\Gamma_N) \) defines an element \( \bar{u}(t) \in H^{1,0}_D(\Omega) \), see Remark 3.2. Thus, the first assertion follows from Theorem 3.7 and
the uniform boundedness of \( \sigma \).

ii) Let \( \zeta, \tilde{\zeta} \in L^\infty(S; L^\infty(\Omega)) \) be fixed, but arbitrary. For almost all \( t \in S \), we estimate

\[
\|\tilde{\varphi} - \varphi\|_{H^2_{D,q}} = \|[(\nabla \cdot \sigma(\zeta(t) + \nu T_0(t))\nabla)^{-1} - (\nabla \cdot \sigma(\zeta(t) + \nu T_0(t))\nabla)^{-1}]\tilde{u}(t)\|_{H^2_{D,q}}
\]

\[
= \|[(\nabla \cdot \sigma(\zeta(t) + \nu T_0(t))\nabla)^{-1} - (\nabla \cdot \sigma(\zeta(t) + \nu T_0(t))\nabla)^{-1}]\tilde{u}(t)\|_{H^2_{D,q}}
\]

\[
\leq \|[(\nabla \cdot \sigma(\zeta(t) + \nu T_0(t))\nabla)^{-1} - (\nabla \cdot \sigma(\zeta(t) + \nu T_0(t))\nabla)^{-1}]\tilde{u}(t)\|_{H^2_{D,q}}
\]

\[
\|\sigma(\zeta(t) + \nu T_0(t)) - \sigma(\zeta(t) + \nu T_0(t))\|_{L^{\infty}(\Omega)}\|\tilde{u}(t)\|_{H^2_{D,q}}
\]

\[
\leq \|[(\nabla \cdot \sigma(\zeta(t) + \nu T_0(t))\nabla)^{-1} - (\nabla \cdot \sigma(\zeta(t) + \nu T_0(t))\nabla)^{-1}]\tilde{u}(t)\|_{H^2_{D,q}}
\]

\[
L_\sigma \|\tilde{\zeta} - \zeta\|_{L^\infty(S; L^\infty(\Omega))}\|\tilde{u}(t)\|_{H^2_{D,q}},
\]

where \( L_\sigma \) denotes the Lipschitz constant of \( \sigma \). Thus the proof is complete. \( \Box \)

**Remark 3.10.** Please notice that non of these estimates depends on the interval \( S \) nor on the initial value \( \theta_0 \in L^\infty(\Omega) \).

The next lemma incorporates the right hand side of the parabolic equation (3.9) into the fixed point mapping.

**Lemma 3.11.** The mapping

\[
G : L^\infty(S; L^\infty(\Omega)) \ni \zeta \mapsto \sigma(\zeta + \nu T_0)\nabla J(\zeta) \cdot \nabla J(\zeta) \in L^\infty(S; L^{\eta/2}(\Omega))
\]

is Lipschitzian and its image is contained in a ball \( M \subset L^\infty(S; L^{\eta/2}(\Omega)) \).

**Proof.** Suppose that \( \varphi, \tilde{\varphi} \in H^1_{D,q}(\Omega) \) and \( \theta \in \mathbb{R} \) are fixed but arbitrary. Using Minkowski’s and Hölder’s inequality, we find

\[
\left( \int_\Omega |(\sigma(\theta)\nabla \varphi) \cdot \nabla \varphi - (\sigma(\theta)\nabla \tilde{\varphi}) \cdot \nabla \tilde{\varphi}|^{\eta/2} \right)^{2/q} \leq \left( \int_\Omega \left( |(\sigma(\theta)\nabla \varphi) \cdot \nabla \varphi| + |(\sigma(\theta)\nabla \varphi - \tilde{\varphi}) \cdot \nabla \tilde{\varphi}| \right)^{\eta/2} \right)^{2/q}
\]

\[
\leq \sigma_1 \left( \int_\Omega |\nabla \varphi|^{\eta} \, dx \right)^{1/q} + \left( \int_\Omega |\nabla \tilde{\varphi}|^{\eta} \, dx \right)^{1/q} \left( \int_\Omega |\nabla \varphi - \tilde{\varphi}|^{\eta} \, dx \right)^{1/q}.
\]

Now let \( \zeta, \tilde{\zeta} \in L^\infty(S; L^\infty(\Omega)) \) be fixed but arbitrary. Hence \( J(\zeta), J(\tilde{\zeta}) \in B \subset L^\infty(S; H^1_{D,q}) \). In view of (3.13), we then find

\[
\|\sigma(\zeta + \nu T_0)\nabla J(\zeta) \cdot \nabla J(\zeta) - (\sigma(\zeta + \nu T_0)\nabla J(\tilde{\zeta}) \cdot \nabla J(\tilde{\zeta})\|_{L^\infty(S; L^{\eta/2})}
\]

\[
\leq \|\sigma(\zeta + \nu T_0)\nabla J(\zeta) \cdot \nabla J(\zeta) - (\sigma(\zeta + \nu T_0)\nabla J(\tilde{\zeta}) \cdot \nabla J(\tilde{\zeta})\|_{L^\infty(S; L^{\eta/2})}
\]

\[
\|\sigma(\zeta + \nu T_0) - \sigma(\zeta + \nu T_0)\|_{L^\infty(S; L^{\eta/2})}
\]

\[
\leq \sigma_1 \left( \int_\Omega |J(\zeta)| \, dx \right)^{1/q} + \left( \int_\Omega |J(\tilde{\zeta})| \, dx \right)^{1/q} \left( \int_\Omega |J(\zeta) - J(\tilde{\zeta})| \, dx \right)^{1/q}.
\]

Thus, Lemma 3.9 gives the first assertion. \( \Box \)

**Remark 3.12.** An inspection of the above arguments shows that neither the radius of \( M \) nor the Lipschitz constant depend on the initial value \( \theta_0 \in L^\infty(\Omega) \) or the interval \( S \).
For the definition of the solution operator associated to the parabolic equation, which is the last part of our fixed point mapping (cf. (3.11)), some essential results on semigroup theory and maximal parabolic regularity are required. For convenience of the reader, we collect these in the sequel. The associated proofs are postponed to Appendix A.

**Lemma 3.13.** Let $A$ be a generator of an analytic semigroup on a Banach space $X$ and $0 \notin \text{spec}(A)$ (so that the graph norm on $D$ induced by $A$ is equivalent to the norm $\|A \cdot \|_X$). Then there holds:

i) For every $x \in X$ and every $T_0, T_1 \in ]0, \infty[$ the function

$$\mathcal{T}_{T_0, T_1} \ni t \mapsto e^{-tA}x \in \mathcal{D}$$

is Lipschitzian.

ii) If $x \in [X, \mathcal{D}]_\tau$ and $\rho \in ]0, \tau]$, then the function

$$\mathcal{T}_{0, T} \ni t \mapsto e^{-tA}x \in [X, \mathcal{D}]_\rho$$

is from $C^{r-\rho}(]0, T]; [X, \mathcal{D}]_\rho)$ for any finite $T > 0$.

The proof of Lemma 3.13 is fairly standard and stated in Appendix A. Let us next recall the concept of maximal regularity and point out some basic facts on this:

**Definition 3.14.** Let $X$ be a Banach space and $A$ be a closed operator with dense domain $D \subset X$ and $S = [T_0, T_1] \subset \mathbb{R}$ a bounded interval. Suppose $r \in ]1, \infty]$. Then we say that $A$ satisfies maximal parabolic $L^r(S; X)$-regularity iff for any $f \in L^r(S; X)$ there is a unique function $w \in W^{1,r}_0(S; X) \cap L^r(S; \mathcal{D})$ which satisfies

$$\frac{\partial w}{\partial t} + Aw = f.$$ (3.16)

**Remark 3.15.** The following things on maximal parabolic $L^r(S; X)$-regularity are known:

i) If $A$ satisfies maximal parabolic $L^r(S; X)$-regularity, then it does so for any other (bounded) interval (see [11]).

ii) If $A$ satisfies maximal parabolic $L^r(S; X)$-regularity, then it satisfies maximal parabolic $L^s(S; X)$-regularity for all $s \in ]1, \infty]$, see [26] or [11].

iii) There is a continuous injection

$$\mathcal{E} : W^{1,r}_0(S; X) \cap L^r(S; \mathcal{D}) \hookrightarrow C(\bar{S}; (X, \mathcal{D}))_{1-\frac{1}{r}},$$

see [1, Ch. III, Thm. 4.10.2], see also [27, Ch. 1.8].

**Lemma 3.16.**

i) Assume that $A$ satisfies maximal parabolic $L^r(S; X)$-regularity. Let $\mathcal{L}$ be the operator which assigns to any right hand side $f \in L^r(S; X)$ the solution $w \in W^{1,r}_0(S; X) \cap L^r(S; \mathcal{D})$ of (3.16). Then the norm of $\mathcal{L}$ does not increase when the interval length shrinks.

ii) Let $\mathcal{E}_0$ denote the restriction of $\mathcal{E}$ to the subspace $\{ \psi : \psi(T_0) = 0 \}$, then the norm of $\mathcal{E}_0$ does not increase if the interval length shrinks.

As the proof of Lemma 3.13, the corresponding proof is postponed to Appendix A. We continue with the following lemma.
**Lemma 3.17.**

i) For any \( \eta \in ]0, 1 - \frac{1}{q} [ \) there is a continuous embedding
\[
(X, \mathcal{D})_{1 - \frac{1}{q}, r} \hookrightarrow [X, \mathcal{D}]_\eta
\]
and, consequently, a continuous embedding
\[
\mathcal{E}_C : C(S; (X, \mathcal{D})_{1 - \frac{1}{q}, r}) \hookrightarrow C(S; [X, \mathcal{D}]_\eta).
\]

ii) The norm of \( \mathcal{E}_C \mathcal{E}_0 \mathcal{L} \) does not increase if the interval length shrinks.

iii) Assume \( \tau \in ]0, 1 - \frac{1}{q} [ \). Then there is an index \( q \) such that \( W^{1, q}(S; X) \cap L^r(S; \mathcal{D}) \) even continuously embeds into \( C^0(S; [X, \mathcal{D}]_r) \).

The proof is based on the theory of interpolation spaces and also depicted in Appendix A. The last auxiliary result on parabolic equations concerns an a priori estimates for the function \( t \), as defined in Remark 3.1. The associated proof is based on the theory of semigroups and presented in Appendix A.

**Lemma 3.18.** Let us (as above) denote the function \([0, \infty]) \ni t \mapsto e^{-tK} \theta_0\) by \( \iota \), where \( K \) is as defined in (3.4).

i) If \( \theta_0 \in L^\infty \), then \( \iota \) admits the estimate \( \|e^{-tK}\theta_0\|_{L^\infty} \leq \|\theta_0\|_{L^\infty} \). For \( t > 0 \)
\( \iota(t) \) even belongs to \( H^{1, q} \) and the restriction of \( \iota \) to any interval \([T_0, T_1]\) with
\( 0 < T_0 < T_1 < \infty \) is Lipschitz continuous if \( t \) is considered as \( H^{1, q}\)-valued.

ii) If \( \theta_0 \in H^{\infty, q}(\Omega) \) with \( \varsigma > \frac{2}{q} \), then \( \iota \) takes its values in a Hölder space \( C^0(\Omega) \)
and is Hölderian in time when considered as \( C^0(\Omega)\)-valued.

In order to apply the concept of maximal parabolic regularity to our situation, we need the following result:

**Theorem 3.19.** There is a \( q_1 \in ]2, 4 [ \) such that for every \( q \in ]2, q_1 \) and every \( S \subset ]0, T[ \)
the operator \( K \), defined in (3.4), satisfies maximal parabolic \( L^r(S; H^{1, q}_\Omega)\)-regularity
with \( H^{1, q} \) being the domain \( \mathcal{D} \) of \( K \).

**Proof.** The theorem is proved in [17] for the case \( r = q \); namely it is first shown if
only \( A = -\nabla \cdot \kappa \nabla \) and afterwards extended to perturbed operators \( A + F \) provided
that \( F \) is a mapping from \( H^{1, 2}(\Omega) \) into \( H^{-1, q}(\Omega) \), see Remark 5 of [17]. That this
is indeed the case for the \( \alpha \)-term in (3.4) was shown in Remark 3.2 b). The case of
arbitrary \( r \in ]1, \infty[ \) is obtained by Remark 3.15 ii).

**Remark 3.20.** In all what follows, let \( q \) be a fixed number in \( ]2, \min(q_0, q_1, 4] \), where
\( q_0 \) where \( q_0 \) is the number \( q_0 \) from Theorem 3.7 associated to \( \sigma_0 \) and \( \sigma_1 \).

Following the notation of Lemma 3.16, we denote by \( \mathcal{L} \) the operator that assigns to a given right hand side \( f \in L^r(S; H^{1, q}_\Omega) \) the solution \( \zeta \in W^{1, r}_0(S; H^{1, q}_\Omega) \cap L^r(S; H^{1, q}) \) of
\[
\frac{\partial \zeta}{\partial t} + K\zeta = f.
\]

Since \( K \) satisfies maximal parabolic \( L^r(S; H^{1, q}_\Omega)\)-regularity, \( \mathcal{L} \) is well defined and the
assertions of Lemma 3.16, and 3.17 hold with \( X = H^{1, q}_\Omega \) and \( \mathcal{D} = H^{1, q}_\Omega \).

**Lemma 3.21.** Let \( \mathcal{F} \) denote the mapping
\[
L^\infty(S, L^{q/2}) \ni f \mapsto f + \tilde{\alpha} \in L^r(S, H^{1, q}_\Omega).
\]
(via the embedding \( L^{q/2} \hookrightarrow H^{-1, q}_\Omega \)) and define \( \mathcal{K} := \mathcal{E}_C \mathcal{E}_0 \mathcal{L} \mathcal{F} \). Then \( \mathcal{K} \) is Lipschitzian
and its Lipschitz constant tends to zero as \( (T_1 - T_0) \to 0 \), i.e. with shrinking time interval length.
Proof. Let $f, \tilde{f} \in L^\infty(S, L^{n/2})$ be given. The maximal parabolic regularity of $K$ then implies
\[
\|K(f) - K(\tilde{f})\|_{C(S;[b,c])} \leq \|\mathcal{E}_c\mathcal{E}_b\|_{L^{q}((S,X),L^{q}([b,c]))} \|F(f) - F(\tilde{f})\|_{L^{q}([b,c],H^{-1,q})}
\leq c|T_1 - T_0|^{|r|/2} \|f - \tilde{f}\|_{L^\infty(S, L^{n/2})},
\]
with a constant $c$ independent of $|S| = |T_1 - T_0|$ because of Lemma 3.17.

With the above results we can now prove the contractivity of the fixed point mapping, as indicated at the beginning of this section. For this purpose, we consider the combined mapping
\[
\mathcal{K}\mathcal{G} : L^\infty([T_0,T_1];L^\infty(\Omega)) \to L^\infty([T_0,T_1];L^\infty(\Omega))
\]
and show that it is strictly contractive if $T_1 - T_0$ is sufficiently small. Here $\mathcal{G}$ is the operator, defined in Lemma 3.11. In order to prove contractivity, let us define the number $r$ as $r > \frac{2q}{q-2}$. Please notice that the interval $[\frac{1}{2}, \frac{1}{q}, 1 - \frac{1}{r}]$ is then not empty due to $q > 2$. Assume now $\eta \in \left[\frac{1}{2}, \frac{1}{q}, 1 - \frac{1}{r}\right]$, then $2\eta - 1 > \frac{2}{q}$ and, hence,
\[
[H^{-1,q},H^{1,q}]_\eta = H^{2\eta-1,q} \hookrightarrow C^\infty(\Omega) \hookrightarrow L^\infty(\Omega) \tag{3.18}
\]
with $\zeta := 2\eta - 1 - \frac{2}{q} > 0$, see [27, Ch. 4.6.1]. Due to Lemma 3.11, Lemma 3.21, and (3.18), $\mathcal{K}\mathcal{G}$ is well defined and, for all $\zeta, \tilde{\zeta} \in L^\infty(S; L^\infty(\Omega))$ there holds
\[
\|\mathcal{K}\mathcal{G}(\zeta) - \mathcal{K}\mathcal{G}(\tilde{\zeta})\|_{L^\infty(S; L^\infty(\Omega))} \leq c|T_1 - T_0|^{1/r} \|\zeta - \tilde{\zeta}\|_{L^\infty(S; L^\infty(\Omega))}.
\]
Thus $\mathcal{K}\mathcal{G}$ is contractive if $T_1 - T_0 < \varepsilon$ provided that $\varepsilon$ is sufficiently small. Therefore, the fixed point equation $\zeta = \mathcal{K}\mathcal{G}(\zeta)$ must have a unique solution by Banach’s contraction principle if $\varepsilon$ is small enough. Please notice that $\varepsilon$ does neither depend on $T_0$ nor on $\theta_0$. Moreover, by construction, this fixed point equation is equivalent to the following system of operator equations on $[T_0, T_0 + \varepsilon]$
\[
\frac{\partial \zeta}{\partial t} + K \zeta = (\sigma(\zeta + \nu)\nabla \varphi) \cdot \nabla \varphi + \tilde{\alpha} \quad \text{in } H^{-1,q}_\Omega \tag{3.19}
\]
\[
-\nabla \cdot (\sigma(\zeta + \kappa)\nabla \varphi) = \tilde{u} \quad \text{in } H^{-1,q}_D.
\]
Hence, the fixed point is identical with the unique solution
\[
\varphi \in L^\infty([T_0, T_0 + \varepsilon]; H^{1,q}_D)
\]
\[
\zeta \in W^{1,r}_0([T_0, T_0 + \varepsilon]; H^{-1,q}_\Omega) \cap L^r([T_0, T_0 + \varepsilon]; H^{1,q}_\Omega)
\]
of (3.19). Choosing $T_0 = 0$, the corresponding solution coincides with the one of Definition 3.3 with $T = \varepsilon$. The property $\theta \in L^r([0, \varepsilon]; H^{1,q}_\Omega)$ ensures the existence of a point $t \in [\varepsilon/2, \varepsilon]$ such that $\theta(t) \in H^{1,q}(\Omega) \hookrightarrow L^\infty(\Omega)$. Hence, we may start once more, i.e. consider (3.19), this time with $T_0 = t$. By the contractivity of $\mathcal{K}\mathcal{G}$, we again obtain a unique solution of (3.19) on $[t, t + \varepsilon]$, which together with the solution on $[0, t]$ represents the solution of (3.9) and (3.10) on $[0, t + \varepsilon]$. Finally, repeating this argument yields the unique existence of a solution according to Definition 3.3 on $[0, T]$. Furthermore, part iii) of Theorem 3.5 follows from Lemma 3.17 iii) and (3.18), and part iv) is obtained from Lemma 3.18 ii).

4. Existence of an optimal control. Let us now turn to the optimal control problem (P) and show that it admits a solution, i.e. a global optimum. Since the state
equation is nonlinear, we can naturally not expect uniqueness of an optimal solution.

We start with the definition of the state space

**Definition 4.1.** Let \( q \) be the real number from Section 3, hence \( q \in [2, \min\{q_0, q_1\}] \), while \( r \) satisfies \( 2q/(q - 2) < r \leq \infty \). Then the state space is defined by

\[
Y := W^{1,r}(0,T; H^{-1,0}_D) \cap L^r(S; H^{1,0})
\]

and thus coincides with the space given in Definition 3.3.

**Definition 4.2.** Based on Theorem 3.5. we introduce the control-to-state operators \( S : L^\infty([0,T]; L^2(\Gamma_N)) \to Y \times L^\infty([0,T]; H^{-1,q}_D) \) and \( S_1 : L^\infty([0,T]; L^2(\Gamma_N)) \to L^\infty([0,T]; L^2(\Gamma_N)) \to \mathbb{R} \) by

\[
S(u) = \begin{pmatrix} S_1(u) \\ S_2(u) \end{pmatrix} = \begin{pmatrix} S_1(u) \\ \varphi(u) \end{pmatrix}
\]

where \( \theta(u) \) and \( \varphi(u) \) denote the solution (1.1)–(1.7) associated to \( u \) in the sense of Definition 3.3. Moreover, \( S_1 : L^\infty([0,T]; L^2(\Gamma_N)) \to Y \) and \( S_2 : L^\infty([0,T]; L^2(\Gamma_N)) \to L^\infty([0,T]; H^{-1,0}_D) \) denote the components of \( S \). We point out that in all what follows \( S \) is sometimes used with different ranges, for simplicity also denoted by \( S \). Using \( S_1 \) we define the reduced objective functional \( j : L^\infty([0,T]; L^2(\Gamma_N)) \to \mathbb{R} \) by

\[
j(u) := J(S_1(u), u),
\]

where \( J \) is the objective functional of \( (P) \).

**Definition 4.3.** A function \( u \in L^\infty([0,T]; L^2(\Gamma_N)) \) is called feasible for \( (P) \) if it satisfied \( 0 \leq u(x,t) \leq u_{\text{max}}(x,t) \) a.e. in \( Q \) and \( S_1(u)(x,t) \leq \theta_{\text{max}}(x,t) \) a.e. in \( Q \). Moreover, the sets \( U^{(c)}_{ad} \) and \( U^{(s)}_{ad} \) are defined by

\[
U^{(c)}_{ad} = \{ u \in L^\infty([0,T], L^2(\Gamma_N)) : 0 \leq u(x,t) \leq u_{\text{max}}(x,t) \text{ a.e. in } \Sigma_N \},
\]

\[
U^{(s)}_{ad} = \{ u \in U^{(c)}_{ad} : S_1(u)(x,t) \leq \theta_{\text{max}}(x,t) \text{ a.e. in } \Sigma_N \}.
\]

**Theorem 4.4.** Let Assumption 2.1–2.4 be fulfilled and assume that there is at least one feasible control. Then there exists an optimal solution of problem \( (P) \).

**Proof.** Since there is a feasible control and the objective functional \( J \) is clearly bounded from below, there is a minimizing sequence of feasible controls, denoted by \( \{ u_n \} \). Moreover, \( \{ u_n \} \) is clearly bounded in \( L^r([0,T], L^2) \) due to the control constraints. Hence there is a weakly converging subsequence, also for simplicity denoted by \( \{ u_n \} \), i.e. \( u_n \rightharpoonup \bar{u} \) in \( L^r([0,T], L^2) \). Since \( U^{(c)}_{ad} \) is weakly closed, we have \( \bar{u} \in U^{(c)}_{ad} \).

For every \( u \in L^\infty([0,T]; L^2(\Gamma_N)) \), there is a unique solution \( \theta \in L^\infty([0,T]; L^\infty(\Lambda)) \).

In view of the assumptions on \( \sigma \) and Theorem 3.7 ii), we have

\[
\| (\sigma(\theta) \nabla \varphi) \cdot \nabla \varphi \|_{L^\infty([0,T]; L^{3/2})} \leq \sigma_1 \| \varphi \|_{L^\infty([0,T]; H^1_D)} \leq c \| u \|_{L^\infty([0,T]; L^2(\Gamma_N))}^2.
\]

Then the maximal parabolic regularity of \( K \) according to Theorem 3.19 immediately implies

\[
\| S(u) \|_{Y \times L^\infty([0,T]; H^{-1,q}_D)} \leq c \left( \| u \|_{L^\infty([0,T]; L^2(\Gamma_N))}^2 + \| \theta_0 \|_{L^\infty(\Omega)} + \| \alpha \theta_1 \|_{L^\infty([0,T]; L^2(\partial \Omega))} \right)
\]

Hence, the sequence of solutions of (1.1)–(1.7) associated to \( \{ u_n \} \), denoted by \( \{ (\theta_n, \varphi_n) \} \), is uniformly bounded in \( Y \times L^\infty([0,T]; H^{-1,0}_D) \), and hence weakly converging to a
\((\bar{\theta}, \bar{\varphi}) \in Y \times L^r([0,T], H^{1,q}_D)\). Since \(C(\bar{Q})\) is compactly embedded in \(Y\) (due to the compactness of \(C^0([0,T], C^0(\Omega)) \rightarrow C(\bar{Q})\)), we obtain

\[
\theta_n \rightharpoonup \bar{\theta} \text{ in } C(\bar{Q}) \quad \Rightarrow \quad \sigma(\theta_n) \rightharpoonup \sigma(\bar{\theta}) \text{ in } C(\bar{Q}) \tag{4.1}
\]

as \(n \to \infty\). Hence \(\bar{\theta}(x,t) \leq \theta_{\text{max}}(x,t)\) for all \((x,t) \in \bar{Q}\). It remains to show that \(\bar{u}, \bar{\theta}, \) and \(\bar{\varphi}\) satisfy the thermistor equations. Utilizing (4.1) once again, we can pass to the limit in (3.12) to obtain

\[
-\nabla \cdot \sigma(\bar{\theta}(t)) \nabla \bar{\varphi}(t) = \bar{\tilde{u}}(t) \text{ a.e. in } [0,T],
\]

where \(\bar{\tilde{u}}\) is the element of \(L^\infty([0,T]; H^{1,q}_D)\) associated to \(\bar{u}\). Moreover, since the solution to (4.2) is unique for fixed \(\bar{\theta}\), it holds for the same subsequence

\[
\varphi_n(t) \rightharpoonup \varphi(t) \quad \text{weakly in } H^{1,q}_D \quad \text{and strongly in } L^2(\Gamma_N) \text{ for a.a. } t \in [0,T]. \tag{4.3}
\]

Next, we observe that \(\delta \varphi_n := \varphi_n - \bar{\varphi}\) solves

\[
\int_{\Omega} \sigma(\theta_n(t)) \nabla \delta \varphi_n(t) \cdot \nabla v dx = \int_{\Gamma_N} (u_n(t) - \bar{\tilde{u}}(t)) v ds - \int_{\Omega} [\sigma(\theta_n(t)) - \sigma(\bar{\theta}(t))] \nabla \varphi(t) \cdot \nabla v dx \quad \forall v \in H^1_D
\]

for almost all \(t \in [0,T]\). Inserting \(v = \delta \varphi_n\), in view of (4.3), the weak convergence of \(u_n\), together with (4.1) and Assumption 2.3, gives

\[
\nabla \delta \varphi_n(t) \rightharpoonup 0 \quad \text{strongly in } [L^2(\Omega)]^2
\]

By possibly extracting a further subsequence, we have

\[
\nabla \varphi_n(x,t) \rightharpoonup \nabla \bar{\varphi}(x,t) \quad \text{a.e. in } Q \text{ f.a.a. } t \in [0,T].
\]

Owing to the uniform bound on \(\varphi\), by Lebesgue’s convergence theorem we get

\[
\nabla \varphi_n \rightharpoonup \nabla \bar{\varphi} \quad \text{strongly in } L^r([0,T], [L^q(\Omega)]^2)
\]

for any \(r \in [1, \infty]\). Now, we can also pass to the limit in the heat equation and conclude that \(\bar{u}, \bar{\theta}, \) and \(\bar{\varphi}\) indeed fulfill (1.1)–(1.7) in the sense of Definition 3.3. The optimality of \(\bar{u}\) then follows by standard arguments using the lower semicontinuity of the objective functional.

**5. Analysis of the linearized state system.** For the derivation of first-order optimality conditions, it is essential to show the Fréchet-differentiability of the control-to-state operator, mapping \(u\) to \(\theta\) (see Section 6.1 below). In preparation of a corresponding theorem, we now consider the following linearized version of the thermistor problem (1.1)–(1.7)

\[
\begin{align*}
\partial_t \theta' - \text{div}(\kappa \nabla \theta') &= (\sigma'(\theta) \theta' \nabla \varphi) \cdot \nabla \varphi + 2(\sigma(\theta) \nabla \varphi) \cdot \nabla \varphi' + f_1 \quad \text{in } Q \tag{5.1} \\
\nu \cdot \kappa \nabla \theta' + \alpha \theta' &= f_2 \quad \text{on } \partial \Omega \times [0,T] \tag{5.2} \\
\theta'(T_0) &= \theta_0' \quad \text{in } \Omega \tag{5.3}
\end{align*}
\]

\[
\begin{align*}
-\text{div}(\sigma(\theta) \nabla \varphi') &= \text{div}(\sigma'(\theta) \theta' \nabla \varphi) + g_1 \quad \text{in } Q \tag{5.4} \\
\nu \cdot \sigma(\theta) \nabla \varphi' &= -\nu \cdot \sigma'(\theta) \theta' \nabla \varphi + g_2 \quad \text{on } \partial \Omega \setminus \Gamma_D \times [0,T] \tag{5.5} \\
\varphi' &= 0 \quad \text{on } \Gamma_D \times [0,T] \tag{5.6}
\end{align*}
\]
with given functions $\theta$, $\varphi$, $\theta_0$, $f_i$, and $g_i$, $i = 1, 2$, which are specified in the subsequent section (cf. Assumption 5.1). Later on $\theta$ and $\varphi$ will be the solution of the nonlinear state system (1.1)–(1.7) associated to reference control. In the following, we will show that (5.1)–(5.6) admit a unique solution $\theta'$ which is Hölder continuous in space and time. This result is then used to establish Fréchet-differentiability of the solution operator associated to (1.1)–(1.7), see Section 6.1.

5.1. Additional assumptions and existence result. Beside Assumptions 2.1 and 2.3, we need the following assumptions for the discussion of (5.1)–(5.6), in particular an additional hypothesis on $\sigma$.

Assumption 5.1. In addition to Assumptions 2.1 and 2.3, the quantities in (5.1)–(5.6) satisfy:

i) $\theta_0 \in L^\infty(\Omega)$.

ii) $\theta$ and $\varphi$ are fixed functions in $L^\infty([0,T];L^\infty(\Omega))$ and $L^\infty([0,T];H^{-1,\sigma}_D(\Omega))$ with $q \in [2, \min\{q_0, q_1\}]$, where $q_0$ and $q_1$ are the numbers from Theorems 3.19 and 3.7, respectively, (such that $q \in [2, 4]$).

iii) The functions $f_1, f_2, g_1,$ and $g_2$ define elements of $L^s([0,T], H^{-1,\sigma}_D(\Omega))$ and $L^s([0,T], H^{-1,\sigma}_D(\Omega))$, respectively, where $s \in [q/(q - 2), \infty]$.

iv) Each component of the matrix $\sigma = \sigma(x, \theta)$ is continuously differentiable w.r.t. $\theta$ for almost all $x \in \Omega$ and there is a constant $C > 0$ such that $\|\sigma'(x, 0)\|_{B(\mathbb{R}^2)} \leq C$. Furthermore, its derivative is locally Lipschitz continuous, i.e., to every real number $M > 0$, there exists a constant $L(M) > 0$ such that

$$\|\sigma'(x, \tilde{\theta}) - \sigma'(x, \theta)\|_{B(\mathbb{R}^2)} \leq L(M)\|\tilde{\theta} - \theta\|,$$

for all $\tilde{\theta}, \theta \in [-M, M]$ and almost all $x \in \Omega$.

Similarly to Remark 3.2, one verifies that Assumption 5.1 iii) is fulfilled if $f_1, g_1 \in L^s(S; L^{p_1}(\Omega))$, $f_2 \in L^s(S; L^{p_2}(\partial\Omega))$, and $g_2 \in L^s(S; L^{p_2}(\partial\Omega \setminus \Gamma_D))$ hold true with $p_1 \geq 2q/(q + 2)$ and $p_2 \geq q/2$. As before, we denote the associated functionals by $\tilde{f}_i$ and $\tilde{g}_i$, $i = 1, 2$, and define $\check{f} := \tilde{f}_1 + \tilde{f}_2$ and $\check{g} := \tilde{g}_1 + \tilde{g}_2$. Furthermore, Assumption 5.1 implies that the Nemyzki-operator associated to $\sigma'$ is continuous from $L^\infty([0,T]; L^\infty(\Omega))$ to $L^\infty([0,T]; L^\infty(\Omega; B(\mathbb{R}^2)))$ and there holds

$$\|\sigma'(\theta)\|_{L^\infty([0,T]; L^\infty(\Omega; B(\mathbb{R}^2)))} \leq C + L(\|\theta\|_{L^\infty([0,T]; L^\infty(\Omega))})\|\theta\|_{L^\infty([0,T]; L^\infty(\Omega))}. \quad (5.7)$$

Similarly to Section 3.1, we set $\iota'_T(t)(\cdot) = e^{-(t-T_0)}K^{\theta_0}$, $t \geq T_0$, such that $\iota'_T$ exhibits the same properties as $\iota_T$, in particular Lemma 3.18.

Definition 5.2. A pair $(\theta', \varphi')$ is considered as solution of (5.1)–(5.6) if there exist indices $q$ and $s$ satisfying the conditions in Assumption 5.1 ii) and iii) such that $\varphi'$ and $\zeta' := \theta' - \iota'_0$ satisfy

$$\varphi' \in L^s([0,T]; H^{-1,\sigma}_D) \quad \text{and} \quad \zeta' \in \begin{cases} W^{1,s}_D([0,T]; H^{-1,\sigma}_D) \cap L^s([0,T]; H^{-1,\sigma}), & \text{if } s < \infty \\ W^{1,s}_0([0,T]; H^{-1,\sigma}_D) \cap L^{s}(\Omega; H^{-1,\sigma}), & \text{if } s = \infty \end{cases} \quad (5.8)$$

and additionally the following operator equations

$$\partial_t \zeta' + K \zeta' = (\sigma'(\theta)) (\zeta' + \iota'_0) \nabla \varphi' \cdot \nabla \varphi + 2 \sigma(\theta) \nabla \varphi \cdot \nabla \varphi' + \check{f} \quad \text{and} \quad -\nabla \cdot (\sigma(\theta) \nabla \varphi') = \nabla \cdot ((\sigma'(\theta)) (\zeta' + \iota'_0) \nabla \varphi) + \check{g}$$

$$\quad (5.10) \quad (5.11)$$
hold true.

Notice that, due to $H^{1,q}(\Omega) \hookrightarrow L^\infty(\Omega)$, $q > 2$, we have $\sigma'(\theta(t))\theta'(t) \in L^\infty(\Omega)$ for almost all $t \in [0,T]$ such that $\nabla \cdot \sigma'(\theta(t))\theta'(t) \sigma : H^1_D \to H^{-1,q}_D$ is defined as in (3.2).

**Theorem 5.3.**

i) There is a solution of (5.1)–(5.6) in the sense of Definition 5.2.

ii) This solution is unique.

iii) If $s > 2q/(q-2)$ and $\|\theta_0\|_{H^s,q} \leq \|\theta_0\|_{H^s} < \infty$ then $\|\theta\|_{C^0([0,T];C^0(\Omega))}$.

### 5.2. Proof of Theorem 5.3

The proof basically follows the lines of the analysis for the nonlinear state system, investigated in Section 3. Again, $T_0$ and $T_1$ are fixed, but arbitrary numbers satisfying $0 \leq T_0 < T_1 < \infty$ and $S = [T_0,T_1]$. We start with the investigation of the elliptic equation (5.11). Similar to Lemma 3.9, we find the following

**Lemma 5.4.** Let $\gamma$ be defined by $\gamma := \frac{2q}{q-2}$ and $\tilde{g}$ be given in $L^s(S;H^{-1,q}_D)$. Then, the affine linear mapping $\mathcal{H}$ which assigns to every $\zeta' \in L^s(S;L^q)$ the solution $\varphi'$ of

$$
-\nabla \cdot (\sigma(\theta)(\nabla \varphi')) = \nabla \cdot (\sigma'(\theta)(\zeta' + \iota_{T_0})\nabla \varphi) + \tilde{g}
$$

(5.12)

is Lipschitz continuous from $L^s(S;L^q)$ to $L^s(S;H^{-1,2}_D)$. Moreover, the associated Lipschitz constant neither depends on $S$ nor on $\theta_0$.

**Proof.** First of all, we find $1/\gamma + 1/q = 1/2$ such that $\iota_{T_0}' \in L^\infty(\Omega;L^\infty)$ (by Lemma 3.18), $\zeta' \in L^s(S;L^q)$, and $\varphi \in L^\infty(S;H^{-1,q}_D)$ imply $(\zeta' + \iota_{T_0}')\nabla \varphi \in L^s(S;L^{q/2})$. Hence, due to Theorem 3.7, (5.12) admits a unique solution in $L^s(S;H^{-1,2}_D)$ for every $\tilde{g} \in L^s(S;H^{-1,q}_D)$, since $\sigma'(\theta) \in L^\infty(S;L^\infty(\Omega;B(\mathbb{R}_2)))$ according to (5.7). Moreover, one has

$$
\|\varphi' - \varphi\|_{L^s(S;H^{-1,2}_D)} \leq \| - (\nabla \cdot (\sigma(\theta))\nabla)^{-1}\|_{L^\infty(S;B(H^{-1,2}_D;H^{1,2}_D))} \|\nabla \cdot (\sigma'(\theta)(\zeta' - \zeta'))\nabla \varphi\|_{L^s(H^{-1,2}_D)}.
$$

For the latter norm, we find

$$
\|\nabla \cdot (\sigma'(\theta)a(\zeta' - \zeta')\nabla \varphi\|_{H^{-1,2}} = \sup_{\|v\|_{H^{1,2}} = 1} \left| \int_\Omega (\nabla \cdot (\sigma'(\theta)(\zeta' - \zeta'))\nabla \varphi \cdot \nabla v\ dx \right|
$$

$$
\leq \sup_{\|v\|_{H^{1,2}} = 1} \|\sigma'(\theta)\|_{L^\infty(\Omega;B(H^{-1,2}_D;H^{1,2}_D))} \|\zeta' - \zeta\|_{H^{-1,2}_D} \|\nabla \varphi\|_{L^q(\Omega)}
$$

with $\|\sigma'(\theta)\|_{L^\infty} := \|\sigma'(\theta)\|_{L^\infty(\Omega;B(\mathbb{R}^2))}$ which is also used in the sequel. Together with our assumptions on $\sigma$, $\varphi$, and $\theta$, and Theorem 3.7 ii), this implies the assertion. □

Now, we turn to the right hand side of (5.10).

**Lemma 5.5.** The mapping $Q : L^s(S;L^q) \to L^s(S;H^{-1,q}_D)$ with $\gamma$ as in Lemma 5.4, given by

$$
Q : \zeta' \mapsto (\sigma'(\theta)(\zeta' + \iota_{T_0})\nabla \varphi) \cdot \nabla \varphi + 2\sigma(\theta)\nabla \varphi \cdot \nabla \mathcal{H}(\zeta') + \tilde{f},
$$

is Lipschitzian with a Lipschitz constant independent of $S$ and $\theta_0$. 

Proof. Using twice Hölder’s inequality yields for the first part of the image of $Q$
\[\| (\sigma'(\theta)(\tilde{\zeta} - \zeta') \nabla \varphi) \cdot \nabla \varphi \|_{H^1_{\Omega}} \leq \sup_{\|\nu\|_{L^{1/q}} = 1} \| \sigma'(\theta) \|_{L^{\infty}} \| (\nabla \varphi) \|_{L^{1/(q-2)}} \| (\tilde{\zeta} - \zeta') \|_{L^{1/(q-2)}} \]
\[\leq \sup_{\|\nu\|_{L^{1/q}} = 1} \| \sigma'(\theta) \|_{L^{\infty}} \| \varphi \|_{L^1_{\Omega}} \| (\tilde{\zeta} - \zeta') \|_{L^{1/(q-2)}} \]
\[\leq c \| \sigma'(\theta) \|_{L^{\infty}} \| \varphi \|_{L^1_{\Omega}} \| (\tilde{\zeta} - \zeta') \|_{L^{1/(q-2)}}\]
where we used the continuous embedding $H^{1,q'}(\Omega) \hookrightarrow L^{2q/(q-2)}(\Omega)$ for the last estimate. The second part is estimated by
\[\| (\sigma(\theta) \nabla \varphi) \cdot \nabla (H(\zeta')) - H(\zeta) \|_{H^1_{\Omega}} \]
\[\leq \sup_{\|\nu\|_{L^{1/q}} = 1} \| \sigma(\theta) \|_{L^{\infty}} \| \varphi \|_{L^1_{\Omega}} \| (\tilde{\zeta'} - \zeta') \|_{L^{1/(q-2)}} \]
\[\leq \sup_{\|\nu\|_{L^{1/q}} = 1} \| \sigma(\theta) \|_{L^{\infty}} \| \varphi \|_{L^1_{\Omega}} \| (\tilde{\zeta'} - \zeta') \|_{L^{1/(q-2)}}\]
where Lemma 5.4 gives the latter estimate. Based on these estimates, we obtain
\[\| Q(\tilde{\zeta}) - Q(\zeta') \|_{L^{s}(S;H^1_{\Omega})} \]
\[\leq \int_{S} \left( \| (\sigma'(\theta)(\tilde{\zeta} - \zeta') \nabla \varphi) \cdot \nabla \varphi \|_{H_{\Omega}^{1,q}} + 2 \| (\sigma(\theta) \nabla \varphi) \cdot \nabla (\tilde{\zeta'} - \zeta') \|_{H_{\Omega}^{1,1}} \right)^{s} dt^{1/s} \]
\[\leq \left( \| \sigma'(\theta) \|_{L^{\infty}(S;L^{\infty})} \| \varphi \|_{L^{\infty}(S;H^1_{\Omega})} \right)^{s} \left( 2 \| (\sigma(\theta) \nabla \varphi) \cdot \nabla (\tilde{\zeta'} - \zeta') \|_{L^{\infty}(S;L^{1})} \right)^{s} \]
Thanks to our assumptions on $\sigma$, $\theta$, and $\varphi$, the expression in the brackets does not depend on $S$ or $\theta_{0}$.

Similarly to the operator $KG$ in Section 3, we now consider the combined mapping:
\[W := \mathcal{E}_{\infty}Q : L^{s}(S;L^{1}) \rightarrow L^{\infty}(S;L^{1}),\]
where $L : L^{s}(S;H^1_{\Omega}) \rightarrow W^{1,s}(S;H^1_{\Omega})$ is defined as in Lemma 3.16. Moreover, $\mathcal{E}_{\infty}$ denotes the embedding of $W^{1,s}(S;H^1_{\Omega}) \cap L^{s}(S;H^{1,q})$ which is well-defined since $W^{1,s}(S;H^1_{\Omega}) \cap L^{s}(S;H^{1,q})$ is Lipschitz continuous from $L^{s}(S;L^{1})$ to $L^{\infty}(S;L^{1})$ with a Lipschitz constant $L_{W}$ independent of $\theta_{0}$ and $S$. Furthermore, we consider the operator $W_{s} = \mathcal{E}_{s}W$, where $\mathcal{E}_{s} : L^{\infty}(S;L^{1}) \rightarrow L^{s}(S;L^{1})$ denotes associated embedding, and we obtain for its Lipschitz constant:
\[\| W_{s}(\tilde{\zeta}) - W_{s}(\zeta') \|_{L^{s}(S;L^{1})} \leq \int_{S} \left( \| W_{s}(\tilde{\zeta}) - W_{s}(\zeta') \|_{L^{1}} ^{s} dt^{1/s} \right) \]
\[\leq [T_{1} - T_{0}]^{1/s} \| W(\tilde{\zeta}) - W(\zeta') \|_{L^{\infty}(S;L^{1})} \]
\[\leq L_{W} [T_{1} - T_{0}]^{1/s} \| \tilde{\zeta} - \zeta' \|_{L^{\infty}(S;L^{1})}\]
such that $W_{s} : L^{s}(S;L^{1}) \rightarrow L^{s}(S;L^{1})$ is contractive for sufficiently small $T_{1} - T_{0}$. The rest of the proof is completely analogous to the theory in the nonlinear case: by construction, the fixed point equation
\[\zeta' = W_{s}\zeta' \in L^{s}(S;L^{1})\]
is equivalent to the operator equation
\[
\partial_t \zeta' + K \zeta' = (\sigma'(\theta)(\zeta' + \zeta_0') \nabla \varphi) \cdot \nabla \varphi + 2(\sigma(\theta) \nabla \varphi) \cdot \nabla \varphi' + \tilde{f} \\
- \nabla \cdot (\sigma(\theta) \nabla \varphi') = \nabla \cdot (\sigma'(\theta)(\zeta' + \zeta_0') \nabla \varphi) + \tilde{g}.
\]
(5.13)
on \]_T_0, T_1]. Provided that \( T_1 - T_0 \) is small enough, Banach’s contraction principle again yields the existence of a unique fixed point and consequently a solution \( \varphi' \in L^s([T_0, T_1]; H^1_D) \)
\[
\zeta' \in W^{1,s}_0([T_0, T_1]; H^{-1}_\Omega) \cap L^s([T_0, T_1]; H^1_D)
\]
of (5.13). By the same arguments as in Section 3, one can repeat the fixed point technique to obtain a solution on the whole time interval \([0, T]\). As in the nonlinear case, the additional regularity of \( \theta' \), stated in Theorem 5.3 iii), follows from Lemma 3.17 iii), (3.18), and Lemma 3.18. Notice that Lemma 5.4 just implies \( \varphi' \in L^s(S; H^1_D) \). However, similarly to the proof of Lemma 5.4, one obtains
\[
\| \varphi' \|_{L^s(S; H^1_D)} \leq \| - (\nabla \cdot (\sigma(\theta))^{-1} \nabla \varphi) \|_{L^\infty(S, B(H^{-1}_\Omega, H^1_D))} + \| \tilde{g} \|_{L^s(S; H^{-1}_\Omega)} + \| \tilde{g} \|_{L^s(S; H^1_D)} \| \zeta' + \zeta_0' \|_{L^s(S; L^\infty)}
\]
(5.14)
where we used Theorem 3.7 ii) for the last estimate. Now, by Lemma 3.18 i), we have \( \zeta_0' \in L^\infty(S; L^\infty) \). Moreover, due to \( q \geq 2 \), \( \zeta' \in L^s(S; H^1_D) \) implies \( \zeta' \in L^s(S; L^\infty) \) such that \( \varphi' \in L^s(S; H^1_D) \) according to Definition 5.2.

**Remark 5.6.** Suppose that \( (\theta, \varphi) \) is a solution of the nonlinear state system (1.1)–(1.7) in the sense of Definition 3.3. Then, \( (\theta, \varphi) \in C([0, T]; C(\Omega)) \cap L^\infty([0, T]; H^1_D) \) such that Assumption 5.1 ii) is fulfilled. Hence, Theorem 5.3 ensures the existence of a unique solution \( (\theta', \varphi') \in W^{1,s}_0([0, T]; H^{-1}_\Omega) \cap L^\infty([0, T]; H^1_D) \times L^s(S; H^1_D), \)
\[
s > q/(q - 2), \text{ for every right hand side } \tilde{f} \in L^s([0, T]; H^{-1}_\Omega) \text{ and } \tilde{g} \in L^s([0, T]; H^1_D).
\]
Moreover, Theorem 5.3 guarantees \( \theta' \in L^\infty([0, T]; L^\infty) \) provided that \( s > 2q/(q - 2) \). If we further suppose that \( \tilde{g} \) is more regular, i.e., \( \tilde{g} \in L^s([0, T]; H^{1-\rho}_\Omega) \) with \( \rho > s > 2q/(q - 2) \), then an estimate, analogous to (5.14), immediately implies \( \varphi' \in L^s([0, T]; H^1_D) \).

**6. First-order necessary optimality conditions.** We start the derivation of first-order conditions with the Fréchet-differentiability of the control-to-state operator \( S \) (cf. Definition 4.2) in Section 6.1, which is one of the crucial point of the first-order analysis for (P). However, using the analysis for the linearized equation, presented in Section 5, the implicit function theorem yields the desired differentiability of \( S \) as well as of the Lagrange function, which is defined in a standard way, see Definition 6.4 below. Afterwards in Sections 6.2 and 6.3, we reformulate the derivative of Lagrange function by introducing an adjoint PDE system which leads to the first-order necessary optimality conditions in form of a Karush-Kuhn-Tucker (KKT) type optimality system.

For the subsequent we redefine \( S \) by \( S := [0, T] \). Recall that the state space is given by \( Y = W^{1,r}(S; H^{-1}_\Omega) \cap L^s(S; H^1_D) \) with \( r \) and \( s \) as defined in Definition 4.1.

**Definition 6.1.** We define
\[
y(u) := \begin{pmatrix} \zeta(u) \\ \varphi(u) \end{pmatrix} \in Y \times L^\infty(S; H^1_D),
\]
where $\zeta(u)$ and $\varphi(u)$ are the solutions of (3.9) and (3.10) associated to $u$. Moreover, let $A: Y \times L^\infty(S; H^{-1,q}_D) \to L'(S; H^{-1,q}_\Omega) \times L^\infty(S; H^{-1,q}_D)$ be defined by

$$A(y) := \left( \partial_t \zeta + K \zeta - (\sigma(\zeta + \nu) \nabla \varphi) \cdot \nabla \varphi, -\nabla \cdot (\sigma(\zeta + \nu) \nabla \varphi) \right).$$

Hence (1.1)–(1.7) is equivalent to

$$A(y) = \left( \frac{\alpha}{\mathcal{I}u} \right) \quad (6.1)$$

where $\mathcal{I} : L^\infty(S; L^2(\Gamma_N)) \to L^\infty(S; H^{-1,q}_D(\Omega))$ is defined by $\tilde{u} = \mathcal{I}u$ (cf. Remark 3.2). Therefore, in view of Theorem 3.5, (6.1) admits a unique solution for every $u \in L^\infty([0,T]; L^2(\Gamma_N))$.

6.1. Differentiability of the control-to-state mapping. As stated above, we will utilize the implicit function theorem to prove the Fréchet-differentiability of $S$. To this end let us introduce the mapping $T : Y \times L^\infty(S; L^2(\Gamma)) \to L'(S; H^{-1,q}_\Omega) \times L^\infty(S; H^{-1,q}_D)$ by

$$T(y, u) := A(y) - \left( \frac{\alpha}{\mathcal{I}u} \right)$$

and hence, (6.1) is equivalent to $T(y, u) = 0$.

Theorem 6.2. The control-to-state operator $S$ is continuously Fréchet-differentiable from $L^\infty(S; L^2(\Gamma_N))$ to $Y \times L^\infty(S; H^{-1,q}_D)$. Its derivative at the point $u$ in the direction $h \in L^\infty(S; L^2(\Gamma_N))$ is given by the solution of

$$\begin{align*}
\partial_t \theta' - \operatorname{div}(\kappa \nabla \theta') &= (\sigma'(\theta) \theta') \nabla \varphi - 2(\sigma(\theta) \nabla \varphi) \cdot \nabla \varphi', \quad \text{in } Q \\
\nu \cdot \kappa \nabla \theta' + \alpha \theta' &= 0, \quad \text{on } \Sigma \\
\theta'(0) &= 0, \quad \text{in } \Omega \\
-\operatorname{div}(\sigma(\theta) \nabla \varphi') &= \operatorname{div}(\sigma'(\theta) \theta' \nabla \varphi), \quad \text{in } Q \\
\nu \cdot \sigma(\theta) \nabla \varphi' &= -\nu \cdot \sigma'(\theta) \theta' \nabla \varphi + h, \quad \text{on } \Sigma_N \\
\nu \cdot \sigma(\theta) \nabla \varphi' &= -\nu \cdot \sigma'(\theta) \theta' \nabla \varphi, \quad \text{on } (\partial \Omega \setminus \Gamma_N \cup \Gamma_D) \times [0,T] \\
\varphi' &= 0, \quad \text{on } \Sigma_D.
\end{align*}$$

(6.2)–(6.8)

where $(\theta, \varphi) = S(u)$ and $(\theta', \varphi') \in Y \times L^\infty(S; H^{-1,q}_D)$ is a solution in the sense of Definition 5.2.

Proof. We apply the implicit function theorem to $T(y, u)$ to verify the assertion. First, Theorem 3.5 implies that, for every $u \in L^\infty(S; L^2(\Gamma_N))$, there is a $y(u) \in Y \times L^\infty(S; H^{-1,q}_D)$ such that $T(y(u), u) = 0$. Next, we show that $T$ is continuously Fréchet-differentiable with respect to $y$ from $Y \times L^\infty(S; H^{-1,q}_D)$ to $L'(S; H^{-1,q}_\Omega) \times L^\infty(S; H^{-1,q}_D)$. The Nemytski-operator associated to $\sigma$ is Fréchet-differentiable in $L^\infty(S; L^\infty(\Omega; B(\mathbb{R}^2)))$ because of Assumption 5.1 iv), and thus, thanks to the continuous embedding, also from $W^{1,q}(S; H^{-1,q}_D) \cap L'(S; H^{-1,q})$ to $L^\infty(S; L^\infty(\Omega; B(\mathbb{R}^2)))$. Furthermore, the Nemytski-operator $\Phi : L^\infty(S; L^q) \to L^\infty(S; L^{q/2})$, defined by

$$\Phi(v)(x, t) := v(x, t)^2,$$
is clearly continuously Fréchet-differentiable from $L^\infty(S;L^2)$ to $L^\infty(S;L^{6/2})$. Consequently, the chain rule implies the continuous Fréchet-differentiability of $|\nabla \varphi|^2$ from $L^\infty(S;H^{-1,q}_D)$ to $L^\infty(S;L^{6/2})$. Since all other constituents of $T$ are linear and bounded in their respective functions spaces, this gives the continuous Fréchet-differentiability of $T$.

It remains to verify that $\partial_y T(y,u)$ is continuously invertible. Given an arbitrary $g = (g_1,g_2) \in L'(S; H^{-1,q}_D) \times L'(S; H^{-1,q}_D)$, the equation $\partial_y T(y,u) y' = g$ is equivalent to

$$\partial_\theta \zeta' + K \zeta' = (\sigma'(\zeta + \iota_0)\zeta'\nabla \varphi) \cdot \nabla \varphi + 2(\sigma(\zeta + \iota_0)\nabla \varphi) \cdot \nabla \varphi' + g_1$$

$$-\nabla \cdot (\sigma(\zeta + \iota_0)\zeta'\nabla \varphi) = \nabla \cdot (\sigma'(\zeta + \iota_0)\zeta'\nabla \varphi) + g_2$$

with $y' = (\zeta', \varphi')$. We observe that it coincides with (5.10) and (5.11) with $\iota'_0 = 0$, which of course corresponds to $\theta'_0 = 0$. Hence, Theorem 5.3 yields the unique existence of $y'$ in $Y \times L^\infty(S; H^{-1,q}_D)$ (cf. Remark 5.6), giving in turn the invertibility of $\partial_y T(y,u)$. Therefore, the implicit function theorem implies that $y(u)$ is as smooth as $T$ and thus continuously Fréchet-differentiable. The particular form of $S'$ immediately follows from

$$y'(u)h = -\partial_y T(y(u),u)^{-1}\partial_y T(y(u),u)h = \partial_y T(y(u),u)^{-1}\begin{pmatrix} 0 \\ 1h \end{pmatrix}.$$  

Notice that $T$ is linear and continuous and consequently Fréchet-differentiable.

**Remark 6.3.** Based on Theorem 5.3, the system (6.2)–(6.8) is also uniquely solvable if the inhomogeneity is only an element of $L^s(S;H^{-1,q}_D)$. The associated solution is also denoted by $\theta'$ and $\varphi'$, i.e.

$$(\theta', \varphi') \in W_0^{1,s}([0,T]; H^{-1,q}_Q) \cap L^s([0,T]; H^{1,q}_D) \times L^s([0,T]; H^{1,q}_D)$$

solves

$$\partial_\theta \theta' + K \theta' = (\sigma'(\theta)\theta'\nabla \varphi) \cdot \nabla \varphi + 2(\sigma(\theta)\nabla \varphi) \cdot \nabla \varphi'$$

$$-\nabla \cdot (\sigma(\theta)\theta'\nabla \varphi) = \nabla \cdot (\sigma'(\theta)\theta'\nabla \varphi) + \bar{h}. \quad (6.10)$$

Notice however that the above proof cannot be carried out with this notion of solutions to (6.2)–(6.8) since the Nemyzki-operator $\Phi$ is clearly not Fréchet-differentiable from $L^s(S; L^2)$ to $L^s(S; L^{6/2})$.

It is well known that the Lagrange multipliers associated to pointwise state constraints are in general only regular Borel measures, see for instance Casas [5]. Hence we define the Lagrange function associated to (P) as follows:

**Definition 6.4.** The space of regular Borel measures on $\mathcal{Q}$ is denoted by $\mathcal{M}(\mathcal{Q})$. The Lagrange function $\mathcal{L} : L^\infty(S;L^2(\Gamma_N)) \times \mathcal{M}(\mathcal{Q}) \to \mathbb{R}$ associated to (P) is given by

$$\mathcal{L}(u,\mu) = \langle \mathcal{S}_1(u) - \theta_{\text{max}}, \mu \rangle_{C(\mathcal{Q}), \mathcal{M}(\mathcal{Q})},$$

where $j$ is the reduced objective functional defined in Definition 4.2.

**Remark 6.5.** Notice that $\mathcal{L}$ is well defined since, by the Riesz representation theorem, $\mathcal{M}(\mathcal{Q})$ can be identified with the dual space of $C(\mathcal{Q})$ and Theorem 3.5 iv) implies that $\mathcal{S}_1(u) = \theta(u) \in C(\mathcal{Q})$.

**Corollary 6.6.** By the chain rule $\mathcal{L}$ is continuously Fréchet-differentiable w.r.t. $u$ from $L^\infty(S;L^2(\Gamma_N))$ to $\mathbb{R}$, and its derivative at $u \in L^\infty(S;L^2(\Gamma_N))$ in direction
In the next section, we will reformulate the derivative of the right hand side.

We discuss the following equation, which is the formally adjoint system to (5.1)–(5.6):

\[
\begin{aligned}
-\partial_t \vartheta &- \text{div}(\kappa \nabla \vartheta) = (\sigma'(\theta) \vartheta \nabla \varphi) \cdot \nabla \varphi - (\sigma'(\theta) \vartheta \nabla \varphi) \cdot \nabla \psi + f_1 &\quad \text{in } Q \\
\nu \cdot \kappa \nabla \vartheta + \alpha \vartheta &= f_2 &\quad \text{on } \partial \Omega \times [0, T] \\
\vartheta(T) &= \vartheta_T &\quad \text{in } \Omega
\end{aligned}
\]

\[
\begin{aligned}
-\text{div}(\sigma(\theta) \nabla \psi) &= -2 \text{div}(\sigma(\theta) \vartheta \nabla \varphi) + g_1 &\quad \text{in } Q \\
\nu \cdot \sigma(\theta) \nabla \psi &= 2 \nu \cdot \sigma(\theta) \vartheta \nabla \varphi + g_2 &\quad \text{on } (\partial \Omega \setminus \Gamma_D) \times [0, T] \\
\psi &= 0 &\quad \text{on } \Gamma_D \times [0, T].
\end{aligned}
\]

The regularity of the inhomogeneities \(f_1, f_2, g_1,\) and \(g_2\) and of the terminal value \(\vartheta_T\) will be specified in the subsequent. The analysis for (6.12)–(6.17), carried out in the following, mainly relies on a duality argument in the spirit of Amann [2], i.e. we use Theorem 5.3 to prove existence and uniqueness of solutions to (6.12)–(6.17).

**Definition 6.7.** Let \(q\) and \(s\) be a real numbers that satisfy the conditions of Assumption 5.1, and denote their conjugate exponents by \(q'\) and \(s'\) such that

\[q' \in ] \max \{ q_0, q_1 \}, 2[ \quad \text{and} \quad s' \in ] 1/q, 2[;\]

where \(q_0\) and \(q_1\) are the numbers from Proposition 3.7 and Theorem 3.19.

**Definition 6.8.** Let \(q, s \in \mathbb{R}\) satisfy the conditions of Definition 6.7, Then, we set

\[
\begin{aligned}
W_{s'}\Omega := W^{1, s'}(\Omega; H^{-1, q'}_\Omega) \cap L^{s'}(\Omega; H^{1, q'}) \\
W_{s, 0} := W^{1, s}_0(\Omega; H^{-1, q}_\Omega) \cap L^s(\Omega; H^{1, q}).
\end{aligned}
\]

The associated dual spaces are denoted by the superscript *. Moreover, given \(r, m > 1,\) we define

\[
H_{1/r', r}^{1/m} := (H^{-1/m}_\Omega, H^{1, m})_{1/r', r},
\]

where \(r'\) satisfies \(1/r' = 1 - 1/r.\)

Note that, due to the duality properties of real interpolation functors,

\[
\begin{aligned}
H_{1/s, s'}^{1/q'}(\Omega) &\quad = (H^{-1, q'}_\Omega, H^{1, q'}_\Omega)_{1/s, s'} \\
&\quad = (H^{1, q'_1}_\Omega, H^{-1, q'_1}_\Omega)_{1/s', s'} = ((H^{-1/q}_\Omega, H^{1/q}_\Omega)_{1/s', s'})^* = (H_{1/s', s}^{1/q})^*
\end{aligned}
\]

holds true. Let us now define the notion of weak and strong solutions in the spirit of Amann [2].
\textbf{Definition 6.9.} Let \( q \) and \( s \) be numbers according to Definition 6.7. Suppose that the inhomogeneities \( f_1 \) and \( f_2 \) define an element \( \tilde{f} \) of \( L^s(S; H^{-1/q}_\Omega) \), whereas \( g_1 \) and \( g_2 \) are identified with \( \tilde{g} \in L^s(S; H^{-1/q}_\Omega) \). Furthermore, let \( \vartheta_T \) be given in \( H^{-1/2,q}_\gamma \). Then, a pair \((\vartheta, \psi) \in W_{s^*} \times L^s([0, T]; H^{-1/q}_D) \) is said to be a \textbf{strong solution} of (6.12)–(6.17) if it satisfies

1. the following operator equations
\[
-\partial_t \vartheta + K^* \vartheta = (\sigma^\prime(\theta) \vartheta \nabla \varphi) \cdot \nabla \varphi + (\sigma^\prime(\theta) \nabla \varphi) \cdot \nabla \psi + \tilde{f} \quad (6.19)
\]
\[
(\vartheta, \psi) \wedge = -2 \nabla \cdot (\sigma(\theta) \vartheta \nabla \varphi) + \tilde{g} \quad (6.20)
\]

2. and the terminal condition
\[
\vartheta(T) = \vartheta_T. \quad (6.21)
\]

Clearly, since \( \kappa \) and \( \sigma(\theta) \) are symmetric, \( K \) and \( -\nabla \cdot \sigma(\theta) \nabla \) are formally self adjoint, such that \( K^*: H^1(D) \rightarrow H^{-1/q}_\Omega \) and \( (-\nabla \cdot \sigma(\theta) \nabla)^* : H^1(D) \rightarrow H^{-1/q}_\Omega \) are defined analogously to (3.2) and (3.4), respectively. Notice moreover that
\[
W_{s^*} \hookrightarrow C(S, (H^{-1/q}_\Omega, H^1(D))_{1/s^*,q}) = C(S, H^{1/q}_D) \quad (6.22)
\]
(cf. Lemma 3.15, iii)) such that (6.21) is well defined.

\textbf{Definition 6.10.} Let \( f_1 \) and \( f_2 \) define an element \( \tilde{f} \in W_{s,0}^* \), while \( g_1 \) and \( g_2 \) are identified with \( \tilde{g} \in L^s(S; H^{-1/q}_\Omega) \). Moreover, \( \vartheta_T \) is given in \( H^{-1/2,q}_\gamma \) with \( \gamma \) as defined in Assumption 6.7. Then functions \( \vartheta \in L^s(S; H^1(D)) \) and \( \psi \in L^s(S; H^1(D)) \) are said to be a \textbf{weak solution} of (6.12)–(6.17) if they fulfill

\[
\int_S (\partial_t \Theta, \vartheta)_{H^{-1/q}_{\Gamma,\Omega}} dt + \int_{\Sigma} \alpha \Theta \vartheta d\omega dt + \int_Q (\kappa \nabla \Theta \cdot \nabla \vartheta - (\sigma^\prime(\theta) \nabla \varphi) \cdot \nabla \varphi \Theta \vartheta + (\sigma^\prime(\theta) \nabla \varphi) \cdot \nabla \psi \Theta) dx dt = (\Theta, \tilde{f})_{W_{s,0}^*, W_{s,0}^*} + (\Theta(T), \vartheta_T)_{H^{-1/2,q}_\Omega, H^{-1/2,q}_\Omega} \quad \forall \Theta \in W_{s,0} \quad (6.23)
\]
\[
(\vartheta, \psi) \wedge = -2 \nabla \cdot (\sigma(\theta) \vartheta \nabla \varphi) + \tilde{g}. \quad (6.24)
\]

Note that the terminal condition is implicitly incorporated in this definition via the term \((\Theta(T), \vartheta_T)\) which is well defined because of \( W_{s,0} \hookrightarrow C(S, H^{1/q}_D) \) and (6.18) (cf. also [2, Section 7]).

\textbf{Remark 6.11.} Since the set \( \mathcal{D} := C_0^\infty([0, T], C^\infty(\bar{\Omega})) \) is dense in \( W_{s,0} \), (6.23) can equivalently be formulated with \( \mathcal{D} \) as test space.

\textbf{Theorem 6.12.}

i) Under Assumption 6.7, for every right hand side \( \tilde{f} \in W_{s,0}^* \), \( \tilde{g} \in L^s(S; H^{-1/q}_\Omega) \)
and every \( \vartheta_T \in H^{-1/2,q}_\gamma \), there exists a unique weak solution to (6.12)–(6.17) in the sense of Definition 6.10.

ii) If the \( \tilde{f} \) is more regular, i.e. \( \tilde{f} \in L^s(S; H^{-1/q}_\Omega) \), then the weak solution is a strong solution according to Definition 6.9.
Proof. We mainly follow the lines of [2]. Let us start with the derivative of the operator $A$ as given in Definition 6.1. As shown in the proof of Theorem 6.2, $A$ is continuously Fréchet-differentiable from $Y \times L^\infty(S;H_D^1)$ to $L'(S;H_\Omega^{-1,q}) \times L^\infty(S;H_D^{-1,q})$ and its derivative at $y := (\theta, \varphi)$ in direction $w := (\Phi, \Psi)$ is given by

$$A'(y)w = \left( \frac{\partial_t \Theta + K \Theta - (\sigma'(\theta) \Theta \nabla \varphi) \cdot \nabla \varphi - 2(\sigma(\theta) \nabla \varphi) \cdot \nabla \Phi}{-\nabla \cdot (\sigma(\theta) \nabla \Phi) - \nabla \cdot (\sigma'(\theta) \Theta \nabla \varphi)} \right). \quad (6.25)$$

In view of Theorem 5.3 $A'(y)$ is also well defined and, by the open mapping theorem, continuously invertible when considered as an operator from $W_{s,0} \times L^\infty(S;H_D^1)$ to $L'(S;H_\Omega^{-1,q}) \times L^\infty(S;H_D^{-1,q})$ (cf. also Remark 6.3). For simplicity let us denote this operator also by $A'(y)$. Now, set $p = (\vartheta, \psi) \in L^\prime(S;H_\Omega^{-1,q}) \times L^\prime(S;H_D^{-1,q})$. Then the adjoint operator $A'(y)^*: L^\prime(S;H_\Omega^{-1,q}) \times L^\prime(S;H_D^{-1,q}) \to W_{s,0} \times L^\prime(S;H_D^{-1,q})$ is given by

$$\langle A'(y)^* p, w \rangle = \langle \tilde{b}, w \rangle \quad \forall w \in W_{s,0} \times L^\prime(S;H_D^{-1,q}) \quad (6.27)$$

in $L^\prime(S;H_\Omega^{-1,q}) \times L^\prime(S;H_D^{-1,q})$. Now suppose that $\tilde{b}$ takes the form

$$\langle \tilde{b}, w \rangle = \langle \Theta(T), \vartheta \rangle_{H_\Omega^{-1,q},H_\Omega^{1,q}} + \langle \Phi(T), \tilde{w} \rangle_{H_D^{-1,q},H_D^{1,q}}$$

where $\vartheta$ clearly defines an element of $W_{s,0}$ due to the above mentioned embeddings. If one inserts this definition of $\tilde{b}$ and test functions $(\Theta(0), 0)$ and $(0, \Phi)$, respectively, with arbitrary $\Theta$ and $\Phi$ in (6.27), then the definition of $A'(y)^*$ in (6.26) immediately yields part i) of the theorem.

Next assume that $\tilde{f}$ is more regular, i.e. $\tilde{f} \in L^\prime(S;H_\Omega^{-1,q})$ and insert $\Theta(x,t) = z(t) \tilde{v}(x)$ with $z \in C_0^\infty[0,T]$ and $v \in H^{1,q}(\Omega)$ as test function in (6.23) such that

$$\left\langle \int_S \partial_t z \vartheta dt, v \right\rangle_{H_\Omega^{-1,q},H_\Omega^{1,q}} = \left\langle \int_S (-K^* \vartheta + (\sigma'(\theta) \partial \nabla \varphi) \cdot \nabla \varphi + (\sigma'(\theta) \nabla \varphi) \cdot \nabla \psi + \tilde{f} z) dt, v \right\rangle_{H_\Omega^{-1,q},H_\Omega^{1,q}}.$$  

Since $v$ was chosen arbitrary, we have for the distributional derivative of $\vartheta$

$$\partial_t \vartheta(z) = - \int_S \partial_t z \vartheta dt$$

$$= - \int_S (-K^* \vartheta + (\sigma'(\theta) \partial \nabla \varphi) \cdot \nabla \varphi$$

$$+ (\sigma'(\theta) \nabla \varphi) \cdot \nabla \psi + \tilde{f} z) dt \quad \forall z \in C_0^\infty[0,T].$$
Thus, $\bar{\partial}_t \vartheta$ is a regular distribution generated by

$$J := K^* \vartheta - (\sigma'(\vartheta) \partial \nabla \varphi) \cdot \nabla \varphi - (\sigma'(\vartheta) \nabla \varphi) \cdot \nabla \psi - \tilde{f}.$$  

Consequently, if we identify $\bar{\partial}_t \vartheta$ with $J$, (6.19) is obtained. Moreover, this immediately implies that $\bar{\partial}_t \vartheta$ is an element of $L^s(S, H_Q^{-1, q'})$ due to the regularity of $J$. Hence we obtain $\vartheta \in W_{s', q'}$, i.e., the regularity of a strong solution. Thus, with regard to [2, Proposition 5.1], we are allowed to integrate by parts w.r.t. time and obtain

$$\int_S (-\bar{\partial}_t \vartheta + K^* \vartheta - (\sigma'(\vartheta) \partial \nabla \varphi) \cdot \nabla \varphi - (\sigma'(\theta) \nabla \varphi) \cdot \nabla \psi - \tilde{f}, \Theta)_{H^{-1, q', s'}_q, H_{s, s'}} dt$$

$$+ (\Theta(T), \vartheta(T) - \vartheta_T)_{H^{1, q', s'}_{q, s}, H^{1, q'}_{1, s, s'}} = 0 \quad \forall \Theta \in W_{s, 0}.$$  

In view of (6.19), this finally gives the terminal condition (6.21).

Now, let $s > 2q/(q - 2)$ such that

$$H^{1,q}_{1/s', s} = (H^{-1,q}_{1}, H^{1,q}_{1-1/s, s}) \hookrightarrow C(\bar{\Omega})$$

(cf. Lemma 3.17 i) and (3.18)). In addition, Remark 3.15 iii) yields $W_{s, 0} \hookrightarrow C(\bar{Q})$. Since both embeddings are dense, we therefore have

$$\mathcal{M}(\bar{\Omega}) \hookrightarrow H^{1,q}_{1/s', s} \quad \text{and} \quad \mathcal{M}(\bar{Q}) \hookrightarrow W^{q}_{s, 0}$$

provided that $s > 2q/(q - 2)$. Here, $\mathcal{M}(\bar{\Omega})$ and $\mathcal{M}(\bar{Q})$ denote the spaces of regular measures on $\bar{\Omega}$ and $\bar{Q}$, respectively (see Definition 6.4). As in case of $\mathcal{M}(\bar{Q}) \cong C(\bar{Q})^*$, we identify $\mathcal{M}(\bar{\Omega})$ with the dual of $C(\bar{\Omega})$ by the Riesz representation theorem. Consequently, Theorem 6.12 implies the following

**Corollary 6.13.** Assume that $\mu \in \mathcal{M}(\bar{Q})$ is given and that the restriction of $\mu$ on $0 \times \bar{\Omega}$ is zero. Moreover, denote the restrictions of $\mu$ on $Q$, $\Sigma := \partial \Omega \times [0, T]$, and $T \times \Omega$ by $\mu_Q$, $\mu_\Sigma$, and $\mu_T$. Then the equation

$$\bar{\partial}_t \vartheta - \text{div}(\kappa \nabla \vartheta) = (\sigma'(\vartheta) \partial \nabla \varphi) \cdot \nabla \varphi - (\sigma'(\vartheta) \nabla \varphi) \cdot \nabla \psi + \mu_Q \quad \text{in} \ Q$$

$$\nu \cdot \kappa \nabla \vartheta + \alpha \vartheta = \mu_\Sigma \quad \text{on} \ \partial \Omega \times [0, T]$$

$$\vartheta(T) = \mu_T \quad \text{in} \ \Omega$$

$$\text{div}(\sigma(\vartheta) \nabla \psi) = -2 \text{div}(\sigma(\vartheta) \partial \nabla \varphi) \quad \text{in} \ Q$$

$$\nu \cdot \sigma(\vartheta) \nabla \psi = 2 \nu \cdot \sigma(\vartheta) \partial \nabla \varphi \quad \text{on} \ \partial \Omega \times [0, T]$$

$$\psi = 0 \quad \text{on} \ \Gamma_D \times [0, T]$$

admits a unique weak solution $(\vartheta, \psi) \in L^s(S; H^{1,q'}_1) \times L^s(S; H^{1,q'}_2)$, $s' < 2q/(q + 2)$, in the sense of Definition 6.10.

**Remark 6.14.** We point out that, if measures appear on the right hand side of the adjoint equation, then $\vartheta \in L^s(S; H^{1,q'}_1)$ such that no weak differentiability of the adjoint state w.r.t. time can be expected in this case.

**6.3. Derivation of the optimality system.** Now we are in the position to state the first-order necessary optimality conditions for (P). Let us begin with the notion of local optimality:

**Definition 6.15.** A function $\bar{u} \in L^\infty(S; L^2(\Gamma_N))$ is called locally optimal for (P), if there is an $\varepsilon > 0$ such that $j(\bar{u}) \leq j(u)$ holds for all feasible $u \in L^\infty(S; (\Gamma_N))$ with $\|u - \bar{u}\|_{L^\infty(S, L^2(\Gamma_N))} \leq \varepsilon$. 

Recall that the Lagrange function is Fréchet-differentiable w.r.t. $u$ by Corollary 6.6. Hence we continue with the definition of Lagrange multipliers associated to the state constraints in $(P)$.

**Definition 6.16.** Let $\bar{u}$ be a locally optimal solution of $(P)$, then $\mu \in \mathcal{M}(Q)$ is said to be a Lagrange multiplier associated to the state constraints in $(P)$, if

$$
\partial_u L(\bar{u}, \mu)(u - \bar{u}) \geq 0 \quad \forall u \in U_{ad},
$$

$$
\mu \geq 0,
$$

$$
\langle \theta - \theta_{\text{max}}, \mu \rangle_{C(Q), \mathcal{M}(Q)} = 0,
$$

hold true.

Here, (6.35) is equivalent to

$$
\langle y, \mu \rangle_{C(Q), \mathcal{M}(Q)} \geq 0 \quad \forall y \in \{ y \in C(Q) \mid y(x, t) \geq 0 \ \forall (x, t) \in \bar{Q} \}.
$$

Moreover, (6.36) is referred to as complementary slackness conditions in all what follows. The following theorem states the first-order necessary optimality conditions for $(P)$, i.e. the existence of Lagrange multipliers in the sense of Definition 6.16. It is for instance proven by Casas in [5].

**Theorem 6.17.** Assume that $\bar{u}$ is a locally optimal solution of $(P)$ and satisfies the following linearized Slater condition: there exists an interior point $u_0 \in U^{(c)}_{ad}$ and a real number $\delta > 0$ such that

$$
S_1(\bar{u})(x, t) + S_1'(\bar{u})(u_0 - \bar{u})(x, t) \leq \theta_{\text{max}}(x, t) - \delta \quad \forall (x, t) \in \bar{Q}.
$$

Then, there exist a Lagrange multiplier $\mu \in \mathcal{M}(\bar{Q})$ according to Definition 6.16 such that (6.34)–(6.36) are satisfied.

It is well known that a certain constraint qualification is needed to ensure the existence of Lagrange multipliers, as for instance the linearized Slater condition (6.38) (cf. also Zowe and Kurcyusz [28]). Notice that this condition requires to consider the state constraints in $C(\bar{Q})$. Next, let us transform (6.34)–(6.36) into the optimality system of $(P)$ by introducing the adjoint state. To that end, let us consider a fixed, but arbitrary local optimum $\bar{u}$ with associated state $\bar{y} = (\bar{\theta}, \bar{\varphi})$. Moreover, we again denote the derivative of $S$ in an arbitrary direction $h \in L^\infty(S; L^2(\Gamma))$ by $y'$, i.e. $y' = S'(\bar{u})h$. Now, consider $h$ as an element of $L^1(S; H_D^{1,\beta})$ with $q$ and $s$ according to Definition 6.7, i.e. $q \in [2, \min\{\bar{q}_0, q_1\}[$ and $s \in [q/(q - 2), \infty)$. Then $y'$ clearly also solves

$$
A'(\bar{y}) y' = \begin{pmatrix} 0 \\ h \end{pmatrix},
$$

where, as in the proof of Theorem 6.12, $A'(\bar{y})$ is considered as an operator from $W_{s,0} \times L^1(S; H_D^{1,\beta})$ to $L^1(S; H_D^{-1,\beta}) \times L^1(S; H_D^{-1,\beta})$ (which is well defined and continuously invertible, cf. also Remark 6.3). Note that, according to Definition 6.8, $W_{s,0}$ is given by $W_{s,0} = W_0^1(S; H_D^{-1,\beta}) \cap L^1(S; H_D^{1,\beta})$. Now, define $p_1 = (\vartheta_1, \psi_1)$ as solution of

$$
-\vartheta_1 \partial_1 - \text{div}(\kappa \nabla \vartheta_1) = (\sigma' (\bar{\theta}) \partial_1 \nabla \varphi) \cdot \nabla \varphi - (\sigma' (\bar{\theta}) \nabla \varphi) \cdot \nabla \psi_1 \quad \text{in } Q
$$

$$
\nu \kappa \nabla \vartheta_1 + \alpha \vartheta_1 = 0 \quad \text{on } \partial \Omega \times [0, T[.
$$

$$
\vartheta_1(T) = I_D(\chi_D \bar{\theta}(T) - \bar{\theta}_d) \quad \text{in } \Omega
$$

$$
- \text{div}(\sigma(\bar{\theta}) \nabla \psi_1) = -2 \text{div}(\sigma(\bar{\theta}) \partial_1 \nabla \varphi) \quad \text{in } Q
$$

$$
\nu \sigma(\bar{\theta}) \nabla \psi_1 = 2 \nu \sigma(\bar{\theta}) \partial_1 \nabla \varphi \quad \text{on } (\partial \Omega \setminus \Gamma_D) \times [0, T[.
$$

$$
\psi = 0 \quad \text{on } \Gamma_D \times [0, T[.
$$
where \( I_D : L^2(D) \to H^{1,q}_{1/s,s}(\Omega) \) is defined by
\[
\langle I(D)(g) , \Theta \rangle_{H^{1,q}_{1/s,s},H^{1,q}_{1/s,s}} := \int_D g \Theta \, dx, \quad g \in L^2(D), \Theta \in H^{1,q}_{1/s,s},
\]
while \( \chi_D \) is the characteristic function on \( D \). Notice that \( I_D \) is well defined since
\[
H^{1,q}_{1/s,s} = (H^{-1,q}_\Omega, H^{-1,q})_{1-1/s,s} \hookrightarrow H^{2q-1,q}
\]
with \( \eta = 2/q < 1-1/s \) because of \( s > q/(q-2) \) such that \( 2n-1 > 0 \) due to \( q < 4 \). Therefore \( H^{1,q}_{1/s,s} \hookrightarrow L^2(D) \). Theorem 6.12 implies that there is the strong solution \( p_1 \in W^{s}_s \times L^s_s(S; H_{D,q}^{1,q}) \) to (6.40)–(6.45) that satisfies
\[
\langle A(\bar{y})^* p_1, w \rangle = \int_D (\bar{\theta}(T) - \theta_d) \Theta(T) \, dx.
\]
for all \( w = (\Theta, \Phi) \in W_{s,0} \times L^s(S; H_{D,q}^{1,q}) \). Next, assume \( s \in [2q/(q-2), \infty] \) and introduce \( p_2 = (\bar{\theta}_2, \bar{\psi}_2) \in L^s_s(S; H_{D,q}^{1,q}) \times L^s_s(S; H_{D,q}^{2,q}) \) as weak solution of (6.28)–(6.33), where the inhomogeneity \( \mu \) is the Lagrange multiplier associated to the state constraints in (P). Notice in this context that, due to Assumption 2.4 iii), the state constraint is not active at \( t = 0 \). Consequently, the positivity of the Lagrange multipliers and the complementary slackness conditions yield that the restriction of \( \mu \) on \( 0 \times \Omega \) is indeed zero as in case of (6.28)–(6.33). Hence, \( p_2 \) solves
\[
\langle A(\bar{y})^* p_2, w \rangle = \langle (\Theta, \mu)_{C(Q),M(Q)} , w \rangle_{W_{s,0} \times L^s(S; H_{D,q}^{1,q})}
\]
with \( s > 2q/(q-2) \) (such that \( W_{s,0} \hookrightarrow C(Q) \), cf. Corollary 6.13). Thus, together with (6.39), we obtain
\[
\int_D (\bar{\theta}(T) - \theta_d) \Theta(T) \, dx + \langle \theta', (\Theta, \mu)_{C(Q),M(Q)} \rangle = \langle A(\bar{y})^* p_1, y' \rangle + \langle A(\bar{y})^* p_2, y' \rangle = \langle p_1 + p_2, A(\bar{y})y' \rangle
\]
\[
= \langle p_1 + p_2, \left( \begin{array}{c} 0 \\ h \end{array} \right) \rangle = \int_\Sigma (\psi_1 + \psi_2) h \, ds \, dt.
\]
Inserting this in (6.11) and (6.34) and a pointwise evaluation of the arising inequality imply by standard arguments
\[
\bar{u}(x, t) = \Pi_{ad}\left\{ -\frac{1}{J} (\tau_N \psi_1 + \tau_N \psi_2) \right\}, \quad (6.46)
\]
where \( \Pi_{ad} \) denotes the pointwise projection operator on \( U^{(c)}_{ad} \) and \( \tau : L^s(S; H_{D,q}^{1,q}) \to L^s(S; H^{-1/q,q}) \) is the trace operator on \( \Gamma \). In this way, we have proven the following result stating the first-order necessary conditions for (P):

**Theorem 6.18.** Let \( \bar{u} \in L^\infty(S; L^2(\Gamma_N)) \) be a local optimum of (P) with associated state
\[
\bar{y} = (\bar{\theta}, \varphi) \in W^{s_1}(S; H^{-1/q}_\Omega) \cap L^r(S; H^{1,q}) \times L^\infty(S; H_{D,q}^{1,q})
\]
with \( q \in [2, \min\{q_0, q_1\}] \) and \( r > 2q/(q-2) \). Suppose further that a function \( u_0 \in U^{(c)}_{ad} \) exists such that the linearized Slater condition (6.38) is fulfilled. Then there exist a Lagrange multiplier \( \mu \in M(Q) \) and adjoint states
\[
p_1 = (\bar{\theta}_1, \psi_1) \in W^{1,q}([0,T]; H^{-1/q}_\Omega) \cap L^q([0,T]; H^{1,q})
\]
\[
p_2 = (\bar{\theta}_2, \psi_2) \in L^q(S; H^{1,q}) \times L^q(S; H_{D,q}^{1,q})
\]
with $q' = q/(q - 1)$, $s'_1 < q/2$, and $s'_2 < 2q/(q + 2)$, such that the following conditions are satisfied:

- the state equation (1.1)–(1.7) in the sense of Definition 3.3
- the first adjoint equation (6.40)–(6.45) in the sense of Definition 6.9
- the second adjoint equation (6.28)–(6.33) in the sense of Definition 6.10
- the positivity property (6.37) of the multipliers
- the complementary slackness conditions (6.36)
- the projection formula (6.46).

Notice that $\Pi_{ad}$ clearly maps $L^{s^*}(S; H^{1-1/q'} q' (\Gamma_N))$ into $L^{s'}(S; H^{1-1/q'} q' (\Gamma_N))$ such that the generic regularity for a local optimal control is given by

$$\bar{u} \in L^\infty(S; L^2(\Gamma_N)) \cap L^{s'}(S; H^{1-1/q'} q' (\Gamma_N))$$

with $s' < 2q/(q + 2)$, $q' \leq q_{\text{max}} = \min\{q_0, q_1\} < 4$ (see Remark 3.8), such that $s' < 4/3$. In addition, we have $q' \notin [q_{\text{min}}', 2]$, where $q'_{\text{min}}$ is the conjugate exponent to $q_{\text{max}}$. Note further that the optimality system can be simplified by introducing $p = p_1 + p_2$ as an adjoint state, i.e. the weak solution of

$$-\partial_t \bar{\theta} - \text{div}(\kappa \nabla \bar{\theta}) = (\sigma'(\bar{\theta}) \varphi) \nabla \varphi - (\sigma'(\bar{\theta}) \nabla \bar{\theta}) \cdot \nabla \psi + \mu_Q \quad \text{in } Q$$

$$\nu \cdot \kappa \nabla \bar{\theta} + \alpha \bar{\theta} = \mu \Sigma \quad \text{on } \partial \Omega \times ]0, T[$$

$$\bar{\theta}(T) = \mathfrak{I}_D(\chi \bar{\theta}(T) - \theta_d) + \mu_T \quad \text{in } \Omega$$

$$-\text{div}(\sigma(\bar{\theta}) \nabla \psi) = -2 \text{div}(\sigma(\bar{\theta}) \varphi \nabla \bar{\theta}) \quad \text{in } Q$$

$$\nu \cdot \sigma(\bar{\theta}) \nabla \psi = 2 \nu \cdot \sigma(\bar{\theta}) \varphi \nabla \bar{\theta} \quad \text{on } (\partial \Omega \setminus \Gamma_D) \times ]0, T[$$

$$\psi = 0 \quad \text{on } \Gamma_D \times ]0, T[.$$

7. A specific application and numerical tests. As mentioned in the introduction a problem of type (P) for instance arises when optimizing the heat treatment of steel by means of an electric current. This procedure is applied in the automotive industry for the hardening of gear racks as part of the widely-used rack-and-pinion steering. Here the workpiece is heated up by the direct current and then rapidly cooled down by means of water nozzles to produce a hard martensitic outer layer. The aim of the optimization is a uniform heating of the teeth of the gear rack which is essential for the hardening process in order to avoid thermal stress and to guarantee a uniform hardening of the tooth system. Thus the measurement domain $D$ in the objective functional of (P) is the domain which is covered by the teeth of the gear rack. Since it is essential to prevent melting during the hardening process, the bound $\theta_{\text{max}}$ in the state constraint of (P) is given by the melting temperature of the material. In addition, the control constraints in (P) reflect the maximum electrical power that can be induced into the workpiece.

In the following, we report on two numerical tests for this particular application problem. The respective optimality system, described in Theorem 6.18, is solved by means of a projected gradient method fitting to the first-order analysis presented in the preceding sections. While the control constraints are incorporated into the projected gradient method, the pointwise state constraints are regularized by means of a quadratic penalization, see [20] and the references therein. Moreover, the partial differential equations, arising in each step of the optimization algorithm, are discretized by linear finite elements in combination with a semi-implicit time stepping. Furthermore, the control is discretized by piecewise linear and continuous spatial ansatz functions, while piecewise constant ansatz functions are used in time.
For the computational domain we choose the two-dimensional simplified gear rack shown in Figure 7.1. Aside from $\sigma$, the material parameters are constant and chosen to approximate the realistic distributions. The particular values are shown in Table 7.1. Here $C_p$ and $\rho$ refer to the specific heat capacity and the density, respectively, that enter the heat equation via

$$C_p \rho \partial_t \theta - \text{div}(\kappa \nabla \theta) = (\sigma(\theta) \nabla \varphi) \cdot \nabla \varphi,$$

which clearly does not influence the theory since they are assumed to be constant. Notice that all parameters are positive constants such that the hypothesis in Assumptions 2.3, 2.4, and 5.1 are satisfied. Moreover, in this case, the function $\sigma$ is a scalar valued function, only depending on $\theta$, i.e., $\sigma : \mathbb{R} \to \mathbb{R}$, which is given by

$$\sigma(\theta) = \left( a + b \theta + c \theta^2 + d \theta^3 \right)^{-1},$$

with $a = 4.9659 \cdot 10^{-7}$, $b = 8.4121 \cdot 10^{-10}$, $c = -3.7246 \cdot 10^{-13}$, and $d = 6.1960 \cdot 10^{-17}$ (see [10] for details). On $\mathbb{R} \setminus [0, 10000]$, $\sigma$ is smoothly extended such that $0 < \sigma_0 \leq \sigma(\theta) \leq \sigma_1 < \infty$ is satisfied for all $\theta \in \mathbb{R}$. Hence it fulfills the conditions in Assumptions 2.3 and 5.1. Finally, the end time $T$ was set to 2.0 s. The Tikhonov parameter $\beta$ within the objective functional is set to $10^{-13}$ to compensate for the comparatively high values of the control (see below).

In the following two numerical tests are presented differing concerning the inequality constraints in (P). While there are only inequality constraints on the control but not on the state in the first example, we choose $\theta_{\text{max}} = 1800 \text{ K}$ in the second test case. In both cases we set $u_{\text{max}} = 7 \cdot 10^7 \text{ A/m}^2$. Note that both test cases are covered by the above theory, since the control is uniformly bounded in $L^\infty([0, T]; L^2(\Gamma_N))$. In all what follows we refer to the first example as free optimization since no state constraints are present in this case. It serves as reference problem in comparison to the state-constrained case. Figure 7.2 shows a detail of the tooth-system at end time for this case. We observe that the desired temperature of 1500 K is nearly reached. However, since no state constraints are imposed, the material is in danger to melt in the corners of tooth system as Figure 7.4 illustrates. The situation changes, if the temperature is forced to stay below the melting temperature by the additional state constraints in (P). In the second numerical test this is approximately enforced by a quadratic penalty term resulting in a maximum temperature of 1805.1 K in the right corner of the tooth system at $t = 0.26 \text{ s}$. However, in this case, the temperature distribution

\begin{table}[h]
\centering
\begin{tabular}{cccccccc}
                      & $\varrho$ & $C_p$ & $\kappa$ & $\alpha$ & $\theta_0$ & $\theta_1$ & $\theta_d$ \\
\hline
$7900 \text{ kg/m}^2$ & 470 $\text{ J/kg K}$ & 50 $\text{ W/m K}$ & 20 $\text{ W/m}^2 \text{ K}$ & 290 K & 290 K & 1500 K \\
\end{tabular}
\caption{Material parameters within the numerical tests.}
\end{table}
differs more significant from the desired 1500 K compared to the free optimization, as Figure 7.3 shows. This observation appears natural since the inequality constraints on state do not allow for the extreme temperature evolution observed in case of the free optimization. Therefore, it seems that a time interval of 2.0 s is not sufficient for heating up the workpiece to 1500 K before cooling it down if, at the same time, melting should be prevented.

In Figure 7.5 the time evolution of the control $u$ in case of free and state-constrained optimization is depicted. Here the stars refer to the state-constrained case, while the circles represent the free optimization. The values are taken at a fixed, but arbitrary point on $\Gamma_N$. One observes that the time evolution of the control differs significantly between both cases. Moreover, the control significantly decreases in time in both examples. An explanation for this observation is the fact that the current does not flow directly through the teeth. Only the area straight below the tooth system is heated up intensely by the current. Afterwards, heat conduction from this area into the teeth increases the temperature in the tooth system. Thus, to achieve a temperature distribution in the teeth as uniform as possible, it appears reasonable to heat up the area below the teeth comparatively fast to ensure a uniform heat conduction into the teeth. Finally the optimal potential $\varphi$ in the state-constrained case at end time $T = 2.0$ s is shown in Figure 7.6. We observe that the expected decay from cathode to anode is reflected by the numerical computations.

Appendix A. Here, the basic properties of solutions to parabolic equations, mentioned at the beginning of Section 3.1, are proven. We start with Lemma 3.13.
Proof of Lemma 3.13.

i) Based [24, Ch. 2.5], we estimate for \( s, t \in [T_0, T_1] \) with \( s < t \)

\[
\| e^{-sA}x - e^{-tA}x \|_\mathcal{D} = \| Ae^{-sA}x - Ae^{-tA}x \|_X \\
\leq \| Ae^{-\frac{t}{2}A} \|_{\mathcal{B}(X)} \| e^{-\frac{t}{2}A}x - e^{-(t-s)A}e^{-\frac{s}{2}A}x \|_X \\
\leq c \| Ae^{-\frac{t}{2}A} \|_{\mathcal{B}(X)} \| x \|_X |t - s|,
\]

which gives the first assertion.

ii) First one notices that \( \| e^{-tA} \|_{\mathcal{B}(\mathcal{D})} \leq \| e^{-tA} \|_{\mathcal{B}(X)} \) which implies by interpolation that \( \| e^{-tA} \|_{\mathcal{B}(\mathcal{X}_\tau)} \leq \| e^{-tA} \|_{\mathcal{B}(X)} \) for all \( t \in [0, \infty) \) and all \( \tau \in [0, 1] \) (see [27, Ch. 1.2.2 and Ch. 1.9.3]). Now let \( T > 0 \) be given and \( s, t \in [0, T] \), then we have by the reiteration theorem (see [27, Ch. 1.9.3])

\[
\frac{\| e^{-tA}x - e^{-sA}x \|_{\mathcal{X}(\mathcal{D})}}{|t - s|} \leq c \frac{\| e^{-tA}x - e^{-sA}x \|_{\mathcal{X}(\mathcal{D}_\tau)}}{|t - s|^{(1 - \frac{1}{\tau})}} \\
\leq c \left( \sup_{s \in [0, T]} \| e^{-sA} \|_{\mathcal{B}(X)} \right)^{(1 - \frac{1}{\tau})} \frac{\| e^{-tA}x - e^{-sA}x \|_{\mathcal{X}(\mathcal{D}_\tau)}}{|t - s|^{(1 - \frac{1}{\tau})}} \\
\leq 2c \left( \sup_{s \in [0, T]} \| e^{-sA} \|_{\mathcal{B}(X)} \right) \left( \sup_{s \in [0, T]} \| e^{-tA}x - e^{-sA}x \|_{\mathcal{X}(\mathcal{D}_\tau)} \right)^{(1 - \frac{1}{\tau})} \| x \|_{\mathcal{X}(\mathcal{D}_\tau)}.
\]

By a well known theorem (see [27, Ch. 1.13.2] or [23, Prop. 2.2.4 and Rem. 2.2.5]), one has

\[
\sup_{s \in [0, T]} \frac{\| e^{-tA}x - e^{-sA}x \|_{\mathcal{X}(\mathcal{D}_\tau)}}{|t - s|^{(1 - \frac{1}{\tau})}} \leq c_1 \| x \|_{\mathcal{X}(\mathcal{D}_{\tau, \infty})}
\]

with a positive constant \( c_1 \) (independent from \( x \in [X, \mathcal{D}]_\tau \)) and, secondly, the continuous embedding \( [X, \mathcal{D}]_\tau \hookrightarrow (X, \mathcal{D})_{\tau, \infty} \); see [27, Ch. 1.10.3]. Hence, we continue (7.1) by

\[
\frac{\| e^{-tA}x - e^{-sA}x \|_{\mathcal{X}(\mathcal{D})}}{|t - s|^{(1 - \frac{1}{\tau})}} \leq 2c \left( \sup_{t \in [0, T]} \| e^{-sA} \|_{\mathcal{B}(X)} \right) \| x \|_{\mathcal{X}(\mathcal{D}_\tau)},
\]

what proves ii) (see also [1, Ch. II.5.3]).

Proof of Lemma 3.16.

i) During this proof, let \( S, S' \) denote the intervals \([T_0, T_1]\) and \([T_0, T']\), respectively,
Clearly, \( T \) then provides isometric injections
\[
\begin{align*}
L'(S'; X) & \rightarrow L'(S; X) \\
W_0^{1, r}(S'; X) \cap L'(S'; D) & \rightarrow W_0^{1, r}(S; X) \cap L'(S; D) \\
C_0(S'; (X, D)_{1-\frac{r}{r'}}) & \rightarrow C_0(S; (X, D)_{1-\frac{r}{r'}}).
\end{align*}
\]

If we indicate \( \mathcal{L} \) by its interval end and write \( \mathcal{L}_T \) and \( \mathcal{L}_{T'} \), then we have for any \( f \in L'(S'; X) \) the identity \( \mathcal{L}_T f = \mathcal{I} \mathcal{L}_{T'} f \). Thus, one may estimate for any \( f \in L'(S'; X) \)
\[
\| \mathcal{L}_{T'} f \|_{W_0^{1, r}(S; X) \cap L'(S; D)} = \| \mathcal{I} \mathcal{L}_{T'} f \|_{W_0^{1, r}(S; X) \cap L'(S; D)} \leq \| \mathcal{L}_T \| \| \mathcal{I} f \|_{L'(S'; X)} = \| \mathcal{L}_T \| \| f \|_{L'(S'; X)},
\]
which implies \( \| \mathcal{L}_{T'} \| \leq \| \mathcal{L}_T \| \).

ii) Denoting the embedding constant of
\[
W_0^{1, r}(S; X) \cap L'(S; D) \hookrightarrow C_0(S; (X, D)_{1-\frac{r}{r'}})
\]
by \( c_T \), we estimate
\[
\begin{align*}
\| u \|_{C_0(S_1; (X, D)_{1-\frac{r}{r'}})} & = \| \mathcal{I} u \|_{C_0(S(X, D)_{1-\frac{r}{r'}})} \\
& \leq c_T \| \mathcal{I} u \|_{W_0^{1, r}(S; X) \cap L'(S; D)} = c_T \| u \|_{W_0^{1, r}(S_1; X) \cap L'(S_1; D)}.
\end{align*}
\]
Thus, the embedding constant which corresponds to the interval \([T_0, T']\) is at most \( c_T \).

Proof of Lemma 3.17.

i) is obtained from well known embedding theorems, see [27, Ch. 1.3.3 and Ch. 1.10].

ii) Obviously, the norm of \( \mathcal{E}_C \) does not depend on the interval length. This, combined with the Lemma 3.16, gives the assertion.

iii) First of all, the estimate
\[
\| w(t) - w(t_0) \|_X = \left\| \int_{t_0}^{t} w'(s) \, ds \right\| \leq \left( \int_{t_0}^{t} \| w'(s) \|_X \, ds \right)^\frac{1}{2} \left( \int_{t_0}^{t} ds \right)^{\frac{1}{2}} \\
\leq \| w \|_{W^{1, r}(S; X)} | t - t_0 |^{\frac{1}{2}}
\]
implies a continuous embedding from \( W^{1, r}(S; X) \) into \( \mathcal{C}^{\frac{1}{2}}(S; X) \). Let \( \eta \) be a number from \([\tau, 1 - \frac{1}{r}]\). Then, by setting \( \delta = \frac{1}{r} - \frac{1}{\eta} \) and \( \lambda = \frac{\delta}{\eta} \), we obtain by the reiteration theorem for complex interpolation (see [27, Ch. 1.9.3])
\[
\begin{align*}
\| w(t) - w(s) \|_{X, D}|_t & \leq c \| w(t) - w(s) \|_{X, D}|_s | t - s |^{\delta(1-\lambda)} \\
& \leq c \left( \frac{\| w(t) - w(s) \|_X^{1-\lambda}}{| t - s |^{\delta(1-\lambda)}} \right) \left( \frac{\| w \|_{C(S; (X, D)_0)}}{2} \right)^{1-\lambda} \\
& \leq c \| w \|_{W^{1, r}(S; X) \cap L'(S; D)}.
\end{align*}
\]
which completes the proof.

**Proof of Lemma 3.18.**

i) The $L^\infty$ estimate follows from the fact that $K$ generates a contraction semigroup on $L^\infty$, see [14]. Further, $K$ generates an analytic semigroup on $H^{-1,q}$ (see [11] or [18]) and $0$ belongs to its resolvent set because the resolvent is compact and $0$ cannot be an eigenvalue due to Assumption 2.3, see [12, Lemma 1.36]. Hence, the Lipschitz continuity follows from Lemma 3.13 i).

ii) Assume $\vartheta \in ]\frac{2}{q},1]$. We have for $\lambda = \varsigma$ and $\lambda = \vartheta$ the interpolation identity

$$H^{\lambda,q} = [H^{-1,q},H^1,q]_{\frac{\lambda}{1+\lambda}},$$

see [13, Thm. 3.5]. Thus, the supposition $\theta_0 \in H^{-\varsigma,q}(\Omega)$ and Lemma 3.13 ii) imply $\|T_0\|_{[0,T]} \in C^{\frac{1}{2}}([0,T];H^{\vartheta,q})$. An application of the (continuous) embedding $H^{\vartheta,q}(\Omega) \hookrightarrow C^{\vartheta-rac{1}{2}}(\Omega)$ (see [27, Ch. 4.6.1]) then proves the assertion.
