Abstract

In this paper, we investigate optimal control problems for Allen–Cahn equations with singular nonlinearities and a dynamic boundary condition involving singular nonlinearities and the Laplace–Beltrami operator. The approach covers both the cases of distributed controls and of boundary controls. The cost functional is of standard tracking type, and box constraints for the controls are prescribed. Parabolic problems with nonlinear dynamic boundary conditions involving the Laplace–Beltrami operation have recently drawn increasing attention due to their importance in applications, while their optimal control was apparently never studied before. In this paper, we first extend known well-posedness and regularity results for the state equation and then show the existence of optimal controls and that the control-to-state mapping is twice continuously Fréchet differentiable between appropriate function spaces. Based on these results, we establish the first-order necessary optimality conditions in terms of a variational inequality and the adjoint state equation, and we prove second-order sufficient optimality conditions.

1 Introduction

Let \( \Omega \subset \mathbb{R}^N \), \( 2 \leq N \leq 3 \), denote some open and bounded domain with smooth boundary \( \Gamma \) and outward unit normal \( \mathbf{n} \), and let \( T > 0 \) be a given final time. We put \( Q := \Omega \times (0,T) \) and \( \Sigma := \Gamma \times (0,T) \), and we assume that \( \beta_i \geq 0 \), \( 1 \leq i \leq 6 \), are given constants which do not all vanish. Moreover, we assume:

(A1) There are given functions
\[
\begin{align*}
  z_Q &\in L^2(Q), \quad z_{\Sigma} \in L^2(\Sigma), \quad z_{T} \in H^1(\Omega), \quad z_{\Gamma,T} \in H^1(\Gamma), \\
  \tilde{u}_1, \tilde{u}_2 &\in L^\infty(Q) \quad \text{with} \quad \tilde{u}_1 \leq \tilde{u}_2 \quad \text{a.e. in} \ Q, \\
  \tilde{u}_{1r}, \tilde{u}_{2r} &\in L^\infty(\Sigma) \quad \text{with} \quad \tilde{u}_{1r} \leq \tilde{u}_{2r} \quad \text{a.e. in} \ \Sigma.
\end{align*}
\]

We then consider the following (tracking type) optimal control problem:

(CP) Minimize
\[
J((y, y_{\Gamma}), (u, u_{\Gamma})) := \frac{\beta_1}{2} \int_0^T \int_{\Omega} |y - z_Q|^2 \, dx \, dt + \frac{\beta_2}{2} \int_0^T \int_{\Gamma} |y_{\Gamma} - z_{\Sigma}|^2 \, d\Gamma \, dt
\]
\[
+ \frac{\beta_3}{2} \int_0^T \int_{\Omega} |y(\cdot, T) - z_{T}|^2 \, dx \, dt + \frac{\beta_4}{2} \int_0^T \int_{\Gamma} |y_{\Gamma}(\cdot, T) - z_{\Gamma,T}|^2 \, d\Gamma \, dt
\]
\[
+ \frac{\beta_5}{2} \int_0^T \int_{\Omega} |u|^2 \, dx \, dt + \frac{\beta_6}{2} \int_0^T \int_{\Gamma} |u_{\Gamma}|^2 \, d\Gamma \, dt \tag{1.1}
\]
subject to the parabolic initial-boundary value problem with nonlinear dynamic boundary condition

\[ y_t - \Delta y + f'(y) = u \quad \text{a.e. in } Q, \tag{1.2} \]

\[ \partial_n y_{\Gamma} - \Delta y_{\Gamma} + \partial_n y + g'(y_{\Gamma}) = u_{\Gamma}, \quad y_{\Gamma} = y_{\Gamma'}, \quad \text{a.e. in } \Sigma, \tag{1.3} \]

\[ y(\cdot, 0) = y_0 \quad \text{a.e. in } \Omega, \quad y_{\Gamma}(\cdot, 0) = y_{\Gamma0} \quad \text{a.e. on } \Gamma, \tag{1.4} \]

and to the control constraints

\[ (u, u_{\Gamma}) \in \mathcal{U}_{\text{ad}} := \left\{ (w, w_{\Gamma}) \in L^2(Q) \times L^2(\Sigma) : \right. \]

\[ \tilde{u}_1 \leq w \leq \tilde{u}_2 \quad \text{a.e. in } Q, \quad \tilde{u}_{1\Gamma} \leq w_{\Gamma} \leq \tilde{u}_{2\Gamma} \quad \text{a.e. in } \Sigma \}. \tag{1.5} \]

Here, \( y_0 \) and \( y_{\Gamma0} \) are given initial data, \( \Delta y_{\Gamma} \) is the Laplace-Beltrami operator on \( \Gamma \), and the functions \( f, g \) are given nonlinearities, while \( u, u_{\Gamma} \) play the roles of distributed or boundary controls, respectively. Note that we do not require \( u_{\Gamma} \) to be somehow the restriction of \( u \) on \( \Gamma \); such a requirement would be much too restrictive for a control to satisfy.

We remark at this place that for the cost functional to be meaningful it would suffice to only assume that \( z_T \in L^2(\Omega) \) and \( z_{\Gamma,T} \in L^2(\Gamma) \). However, the higher regularity of \( z_T \) and \( z_{\Gamma,T} \) requested in \((A1)\) will later be essential to be able to treat the adjoint state problem.

The system (1.2)–(1.4) is an initial-boundary value problem with nonlinear dynamic boundary condition for an Allen-Cahn equation. In this connection, the unknown \( y \) usually stands for the order parameter of an isothermal phase transition, typically the fraction of one of the involved phases. In such a situation it is physically meaningful to require \( y \) to attain values in the interval \([0, 1]\) on both \( \Omega \) and \( \Gamma \). A standard technique to meet this requirement is to postulate that the first derivatives of the bulk potential \( f \) and of the surface potential \( g \) become singular at 0 and 1. A typical form for such a potential is \( f = f_1 + f_2 \), where \( f_2 \) is smooth on \([0, 1]\) and \( f_1(y) = \alpha \left[ y \ln(y) + (1 - y) \ln(1 - y) \right] \) with some \( \alpha > 0 \). Another possibility is to choose \( f_1 \) as the indicator function \( I_{[0,1]} \) of the interval \([0, 1]\); in this case \( f_1' \) has to be replaced by the subdifferential \( \partial I_{[0,1]} \), and \( f \) becomes a double obstacle potential. In this case, (1.2) has to be understood as a differential inclusion or variational inequality. Similar choices can be made for the surface potential \( g \).

There exists a vast literature on the well-posedness and asymptotic behaviour of the Allen-Cahn equation with the no-flux boundary condition \( \partial_n y = 0 \) in place of (1.3). Also, the well-posedness and asymptotic behavior of the system (1.2)–(1.4) has been the subject of numerous papers (see [3] and the many references given there).

Moreover, distributed and boundary control problems for the Allen-Cahn equation with no-flux boundary conditions or boundary conditions of the third kind have been studied in a number of recent papers, in particular, for the case of the double obstacle potential. In this connection, we refer to [5] and [6]. Associated stationary, that is, elliptic MPEC problems have been studied in [9] (see also the monograph [14]), and the related Cahn-Hilliard case was recently analyzed in [10]. We also like mention the works [7], [8], [12] that treated optimal control problems for the Caginalp-type temperature-dependent generalization of the Allen-Cahn equation in the case of nonsingular potentials and standard boundary conditions; a thermodynamically consistent temperature-dependent model with singular potential of the above logarithmic type was the subject of [13].

The main novelty of the present paper is to study optimal control problems with singular potentials of the logarithmic type and dynamic boundary conditions of the form (1.3). In fact, while various types of dynamic boundary conditions have already been studied in connection with optimal control theory (see
control it does not make sense to postulate that the controls \( u \) and \( u_\Gamma \) satisfy \( u|_\Gamma = u_\Gamma \).

The paper is organized as follows: in Section 2, we give a precise statement of the problem under investigation, and we derive some results concerning the state system (1.2)–(1.4) and a certain linear counterpart, which will be employed repeatedly in the later analysis. In Section 3, we then treat the optimal control problem, proving the existence of optimal controls and deriving the first-order necessary and the second-order sufficient optimality conditions. During the course of this analysis, we will make repeated use of the elementary Young’s inequality

\[
a \, b \leq \gamma |a|^2 + \frac{\gamma}{4} |b|^2 \quad \forall \, a, b \in \mathbb{R} \quad \forall \, \gamma > 0,
\]

of Hölder’s inequality, and of the fact that we have the continuous embeddings \( H^1(\Omega) \subseteq L^p(\Omega) \), for \( 1 \leq p \leq 6 \), and \( H^2(\Omega) \subseteq L^\infty(\Omega) \) in three dimensions of space. In particular, we have

\[
\begin{align*}
\|v\|_{L^p(\Omega)} & \leq \tilde{C}_p \|v\|_{H^1(\Omega)} \quad \forall \, v \in H^1(\Omega), \tag{1.6} \\
\|v\|_{L^\infty(\Omega)} & \leq \tilde{C}_\infty \|v\|_{H^2(\Omega)} \quad \forall \, v \in H^2(\Omega), \tag{1.7}
\end{align*}
\]

with positive constants \( \tilde{C}_p \), \( 1 \leq p \leq \infty \), that only depend on \( \Omega \).

## 2 General assumptions and the state equation

In this section, we formulate the general assumptions of the paper, and we state some results for the state system (1.2)-(1.4). To this end, we introduce the function spaces

\[
\begin{align*}
H & := L^2(\Omega), \quad V := H^1(\Omega), \quad H_\Gamma := L^2(\Gamma), \quad V_\Gamma := H^1(\Gamma), \\
\mathcal{H} & := L^2(Q) \times L^2(\Sigma), \quad \mathcal{X} := L^\infty(Q) \times L^\infty(\Sigma), \\
\mathcal{V} & := \{(y, y_\Gamma) : y \in H^1(0, T; H) \cap C^0([0, T]; V) \cap L^2(0, T; H^2(\Omega)), \\
& \quad y_\Gamma \in H^1(0, T; H_\Gamma) \cap C^0([0, T]; V_\Gamma) \cap L^2(0, T; H^2(\Gamma)), \quad y_\Gamma = y_{\Gamma}|_T \}, \tag{2.1}
\end{align*}
\]

which are Banach spaces when endowed with their natural norms. In the following, we denote the norm in a Banach space \( E \) by \( \| \cdot \|_E \); for convenience, the norm of the space \( H \times H \times H \) will also be denoted by \( \| \cdot \|_H \). Identifying \( H \) with its dual space \( H^* \), we have the Hilbert triplet \( V \subseteq H \subseteq V^* \), with dense and compact embeddings. Analogously, we obtain the triplet \( V_\Gamma \subseteq H_\Gamma \subseteq V_\Gamma^* \), with dense and compact embeddings. We make the following general assumptions:

(A2) \( f = f_1 + f_2 \) and \( g = g_1 + g_2 \), where \( f_2, g_2 \in C^3[0, 1] \), and where \( f_1, g_1 \in C^3(0, 1) \) are convex and satisfy the following conditions:

\[
\begin{align*}
\lim_{r \searrow 0} f'_1(r) & = \lim_{r \searrow 0} g'_1(r) = -\infty, & \lim_{r \nearrow 1} f'_1(r) & = \lim_{r \nearrow 1} g'_1(r) = +\infty. \tag{2.2} \\
\exists \, M_1 & \geq 0, \, M_2 > 0 \text{ such that } |f'_1(r)| \leq M_1 + M_2 |g'_1(r)| \quad \forall \, r \in (0, 1). \tag{2.3}
\end{align*}
\]
Moreover, there is a positive constant \( K \). Suppose that also (ii) exists a bounded open ball in \((A4)\), and the assumption is rather a denotation: once and for all, noting that any other such ball could be used instead. In this sense, the following such that the following holds: whenever \( \beta \) satisfies \( \beta = f'_1, \beta = g'_1, \pi = f'_2, \pi = g_2 \) there.

Theorem 2.1 Suppose that the general assumptions (A2), (A3) are satisfied. Then we have:

(i) The state system (1.2)--(1.4) has for any pair \((u, u_{\Gamma}) \in \mathcal{H}\), a unique solution \((y, y_{\Gamma}) \in \mathcal{Y}\) such that

\[
0 < y < 1 \quad \text{a.e. in} \quad Q, \quad 0 < y_{0r} < 1 \quad \text{a.e. on} \quad \Sigma. \tag{2.4}
\]

(ii) Suppose that also (A4) is fulfilled. Then there is a positive constant \( K^*_1 \), which only depends on \( \Omega, T, y_0, y_{0r}, f, g, \) and \( R \), such that for every \((u, u_{\Gamma}) \in \mathcal{U}\) the associated solution \((y, y_{\Gamma}) \in \mathcal{Y}\) satisfies

\[
\|y\|_{H^1(0,T;\mathcal{H})} + \|y\|_{C^0([0,T];V) \cap L^2(0,T;H^2(\Omega))} + \|y_{\Gamma}\|_{H^1(0,T;\mathcal{H}_r)} + \|y_{\Gamma}\|_{C^0([0,T];V_{\Gamma} \cap L^2(0,T;H^2(\Gamma))}) \leq K^*_1, \tag{2.6}
\]

\[
\|f'(y)\|_{L^2(0,T;\mathcal{H})} + \|g'(y_{\Gamma})\|_{L^2(0,T;H^2_r)} \leq K^*_1. \tag{2.7}
\]

Moreover, there is a positive constant \( K^*_2 \), which only depends on \( \Omega, T, y_0, y_{0r}, f, g, \) and \( R \), such that the following holds: whenever \((u_1, u_{1r}), (u_2, u_{2r}) \in \mathcal{U}\) are given and \((y_1, y_{1r}), (y_2, y_{2r}) \in \mathcal{Y}\) denote the associated solutions of the state system, then we have

\[
\|y_1 - y_2\|_{C^0([0,T];\mathcal{H})} + \|\nabla (y_1 - y_2)\|_{L^2(Q)} + \|y_{1r} - y_{2r}\|_{C^0([0,T];\mathcal{H}_r)} + \|\nabla_{\Gamma} (y_{1r} - y_{2r})\|_{L^2(\Sigma)} \leq K^*_2 \left\{ \|u_1 - u_2\|_{L^2(0,T;\mathcal{H})} + \|u_{1r} - u_{2r}\|_{L^2(0,T;H^2_r)} \right\}. \tag{2.8}
\]
Remark 2: (i) It follows from Theorem 2.1, in particular, that the control-to-state mapping \( S, (u, u_\Gamma) \mapsto S(u, u_\Gamma) := (y, y_\Gamma) \) is well defined as a mapping from \( X \) into \( Y \); moreover, \( S \) is Lipschitz continuous when viewed as a mapping from the subset \( U \) of \( H \) into the space \( (C^0([0, T]; H) \cap L^2(0, T; V)) \times (C^0([0, T]; H_\Gamma) \cap L^2(0, T; V_\Gamma)) \).

(ii) Observe that we cannot expect \( y \) to be continuous in \( \overline{Q} \), since both \( \partial_t y_\Gamma \) and \( \Delta_\Gamma y_\Gamma \) only belong to \( L^2(\Sigma) \), so that also only \( \partial_n y_\Gamma \in L^2(\Sigma) \). However, we have \( y \in L^2(0, T; C^0(\overline{\Omega})) \) and \( y_\Gamma \in L^2(0, T; C^0(\Gamma)) \).

The next result is concerned with a linear problem with dynamic boundary condition. It will later be needed to ensure the solvability of a number of linearized systems.

**Theorem 2.2** Suppose that functions \( (u, u_\Gamma) \in H, c_1 \in L^\infty(Q), c_2 \in L^\infty(\Sigma), w_0 \in H^1(\Omega), \) and \( w_{0_\Gamma} \in H^1(\Gamma) \) are given. Then we have:

(i) The linear initial-boundary value problem

\[
\begin{align*}
  w_t - \Delta w + c_1(x, t) w &= u \quad \text{a.e. in } Q, \\
  \partial_n w + \partial_t u_\Gamma - \Delta_\Gamma u_\Gamma + c_2(x, t) u_\Gamma &= u_\Gamma \quad \text{a.e. on } \Sigma, \\
  w(\cdot, 0) &= w_0 \quad \text{a.e. in } \Omega, \\
  u_\Gamma(\cdot, 0) &= w_{0_\Gamma} \quad \text{a.e. on } \Gamma,
\end{align*}
\]

has a unique solution \( (w, u_\Gamma) \in Y \).

(ii) There exists a constant \( \hat{C} > 0 \), which only depends on \( \Omega, T, \|c_1\|_{L^\infty(Q)}, \) and \( \|c_2\|_{L^\infty(\Sigma)} \), such that the following holds: whenever \( w_0 = 0 \) and \( w_{0_\Gamma} = 0 \) then

\[
\|(w, u_\Gamma)\|_Y \leq \hat{C} \|(u, u_\Gamma)\|_H .
\]

**Proof:** We put \( \beta(w) := \beta_\Gamma(w) := w \) and define the operators

\[
\Pi(w)(x, t) := c_1(x, t) w(x, t) - w(x, t), \quad \Pi_\Gamma(w_\Gamma)(x, t) := c_2(x, t) w_\Gamma(x, t) - w_\Gamma(x, t).
\]

With these definitions, we may rewrite the equations (2.9) and (2.10) in the form

\[
\begin{align*}
  w_t - \Delta w + \beta(w) + \Pi(w) &= u, \\
  \partial_n w + \partial_t u_\Gamma - \Delta_\Gamma u_\Gamma + \beta_\Gamma(u_\Gamma) + \Pi_\Gamma(u_\Gamma) &= u_\Gamma,
\end{align*}
\]

respectively. Since the functions \( \beta \) and \( \beta_\Gamma \) are strictly monotone increasing in \( \mathbb{R} \), the system (2.11), (2.13), (2.14) has almost the same form as the system considered in Theorem 2.5 in [3], the only difference being that here \( \Pi, \Pi_\Gamma \) are linear and continuous operators while \( \pi, \pi_\Gamma \) in [3] were Lipschitz continuous functions. However, a closer inspection of the proof of Theorem 2.5 in [3] reveals that the argumentation used there carries over to the present situation with only minor and obvious modifications. Hence, the asserted existence result is valid.

Now let \( w_0 = 0 \) and \( w_{0_\Gamma} = 0 \). In the following, we denote by \( C_i, i \in \mathbb{N} \), positive constants that only depend on the quantities mentioned in the assertion of (ii). Testing (2.13) by \( w_t \) yields for every
\( t \in (0, T] \) the inequality

\[
\int_0^t \int_\Omega w_t^2 \, dx \, dt + \frac{1}{2} \| w(t) \|_V^2 \, V + \int_0^t \int_\Gamma |\partial_t w_T |^2 \, d\Gamma \, dt + \frac{1}{2} \| w_T(t) \|_{V_T}^2 \\
\leq \int_0^t \int_\Omega \left( (|c_1| + 1)|w| + |u| \right) |w_t| \, dx \, dt + \int_0^t \int_\Gamma \left( (|c_2| + 1)|w_T| + |u_T| \right) |\partial_t w_T | \, d\Gamma \, dt,
\]

whence, using Young’s inequality and the fact that \( c_1 \in L^\infty(Q) \) and \( c_2 \in L^\infty(\Sigma) \), we obtain

\[
\int_0^t \int_\Omega w_t^2 \, dx \, dt + \| w(t) \|_V^2 \, V + \int_0^t \int_\Gamma |\partial_t w_T |^2 \, d\Gamma \, dt + \| w_T(t) \|_{V_T}^2 \\
\leq C_1 \left( \int_0^t \int_\Omega (|w|^2 + |u|^2) \, dx \, dt + \int_0^t \int_\Gamma (|w_T|^2 + |u_T|^2) \, d\Gamma \, dt \right).
\]

Gronwall’s lemma then yields that

\[
\| w \|_{H^1(0,T;H) \cap C^0([0,T];V)} + \| w_T \|_{H^1(0,T;H_T) \cap C^0([0,T];V_T)} \leq C_2 \|(u, u_T)\|_\mathcal{H}.
\] (2.15)

Next, a comparison argument in (2.9) shows that also

\[
\| \Delta w \|_{L^2(0,T;H)} \leq C_3 \|(u, u_T)\|_\mathcal{H}.
\] (2.16)

Now we invoke [1, Theorem 3.1, p. 1.79] with the specifications

\[
A = -\Delta, \quad g_0 = y_T, \quad p = 2, \quad r = 0, \quad s = 3/2,
\]

to conclude that

\[
\int_0^T \| w(t) \|_{H^{3/2}(\Omega)}^2 \, dt \leq C_4 \int_0^T \left( \| \Delta w(t) \|_{H}^2 + \| w_T(t) \|_{V_T}^2 \right) \, dt,
\] (2.17)

whence it follows that

\[
\| w \|_{L^2(0,T;H^{3/2}(\Omega))} \leq C_5 \|(u, u_T)\|_\mathcal{H}.
\] (2.18)

Hence, by the trace theorem, we have that

\[
\| \partial_n w \|_{L^2(0,T;H^1(T))} \leq C_6 \|(u, u_T)\|_\mathcal{H},
\] (2.19)

so that, by comparison in the equation resulting from (2.10), we obtain

\[
\| \Delta_T w_T \|_{L^2(\Sigma)} \leq \|(u, u_T)\|_\mathcal{H}
\] (2.20)

and consequently

\[
\| w_T \|_{L^2(0,T;H^2(\Gamma))} \leq C_9 \|(u, u_T)\|_\mathcal{H}.
\] (2.21)

Now, owing to standard elliptic estimates, we infer

\[
\| w \|_{L^2(0,T;H^2(\Omega))} \leq C_7 \|(u, u_T)\|_\mathcal{H}.
\] (2.22)

This concludes the proof of the assertion. \( \blacksquare \)
Remark 3: It follows from (ii) in Theorem 2.2 that for zero initial data the solution operator \((u, u_{\Gamma}) \mapsto (w, w_{\Gamma})\) is a continuous linear mapping from \(\mathcal{H}\) into \(\mathcal{Y}\).

While it cannot be expected that the solution to the linear system (2.9)–(2.11) is bounded, we now establish a boundedness result for the solution to the nonlinear state system (1.2)–(1.4) that will be of key importance in the subsequent analysis. To this end, we need the following assumption:

\begin{align*}
(A5) \quad y_0 \in L^\infty(\Omega), \ y_{\Gamma_0} \in L^\infty(\Gamma), \text{ and it holds} \quad \begin{aligned}
0 < \operatorname{ess} \inf_{x \in \Omega} y_0(x), \quad &\operatorname{ess} \sup_{x \in \Omega} y_0(x) < 1, \\
0 < \operatorname{ess} \inf_{x \in \Gamma} y_{\Gamma_0}(x), \quad &\operatorname{ess} \sup_{x \in \Gamma} y_{\Gamma_0}(x) < 1. 
\end{aligned} \tag{2.23}
\end{align*}

Lemma 2.3 Suppose that the assumptions (A2)–(A5) are satisfied. Then there are constants \(0 < r_* \leq r^* < 1\), which only depend on \(\Omega, T, y_0, y_{\Gamma_0}, f, g, \) and \(R\), such that we have: whenever \((y, y_{\Gamma}) = S(u, u_{\Gamma})\) for some \((u, u_{\Gamma}) \in U\) then it holds

\begin{align*}
r_* \leq y \leq r^* \ a. e. \ in \ Q, \quad r_* \leq y_{\Gamma} \leq r^* \ a. e. \ in \ \Sigma. \tag{2.24}
\end{align*}

Proof: Let \((u, u_{\Gamma}) \in U\) be arbitrary and \((y, y_{\Gamma}) = S(u, u_{\Gamma})\). Then we have

\[
\|u\|_{L^\infty(Q)} + \|u_{\Gamma}\|_{L^\infty(\Sigma)} \leq R.
\]

By virtue of (2.2) and (2.23), there are constants \(0 < r_* \leq r^* < 1\) such that

\begin{align*}
r_* \leq \min \left\{ \operatorname{ess} \inf_{x \in \Omega} y_0(x), \ operatorname{ess} \inf_{x \in \Gamma} y_{\Gamma_0}(x) \right\}, \tag{2.25}
\end{align*}

\begin{align*}
r^* \geq \max \left\{ \operatorname{ess} \sup_{x \in \Omega} y_0(x), \ operatorname{ess} \sup_{x \in \Gamma} y_{\Gamma_0}(x) \right\}, \tag{2.26}
\end{align*}

\begin{align*}
\max \{f'(r) + R, g'(r) + R\} \leq 0 \quad \forall \ r \in (0, r_*), \tag{2.27}
\end{align*}

\begin{align*}
\min \{f'(r) - R, g'(r) - R\} \geq 0 \quad \forall \ r \in (r^*, 1). \tag{2.28}
\end{align*}

Now define \(w := (y - r^*)^+\). Clearly, we have \(w \in V\) and \(w_{\Gamma} \in V_{\Gamma}\). We put \(w_{\Gamma} := w_{\Gamma}\) and test (1.2) by \(w\). Thanks to (2.26), we readily see that

\[
0 = \frac{1}{2} \|w(T)\|_{H}^2 + \int_0^T \|\nabla w(t)\|_{H}^2 \, dt \\
+ \frac{1}{2} \|w_{\Gamma}(T)\|_{H_{\Gamma}}^2 + \int_0^T \|\nabla_{\Gamma} w_{\Gamma}(t)\|_{H_{\Gamma}}^2 \, dt + \Phi,
\]

where, owing to (2.27) and (2.28),

\[
\Phi := \int_0^T \int_{\Omega} (f'(y) - u) \, w \, dx \, dt + \int_0^T \int_{\Gamma} (g'(y_{\Gamma}) - u_{\Gamma}) \, w_{\Gamma} \, d\Gamma \, dt \geq 0.
\]
In conclusion, \( w = (y - r^*)^+ = 0 \), i.e., \( y \leq r^* \), almost everywhere in \( Q \) and on \( \Sigma \). The remaining inequalities follow similarly by testing (1.2) with \( w := -(y - r^*)^- \).

Observe that in view of (A2) and of Lemma 2.3, we may (by possibly choosing a larger \( K_1^* \)) assume that also

\[
\max_{0 \leq t \leq 3} \left\{ \max \left\{ \| f^{(i)}(y) \|_{L^\infty(Q)}, \| g^{(i)}(y_{1r}) \|_{L^\infty(\Sigma)} \right\} \right\} \leq K_1^*,
\]

whenever \((y, y_{1r}) = S(u, u_{1r})\) for some \((u, u_{1r}) \in U\).

\textbf{Remark 4:} Lemma 2.3 entails that the singular components in the state equations of the control problem (CP) are only active in a domain of arguments where they behave like standard bounded smooth nonlinearities. As a consequence, we could use classical differentiability results to see that both \( f \) and \( g \) generate three times continuously differentiable Nemyskii operators on suitable subsets of \( L^\infty(Q) \) and \( L^\infty(\Sigma) \), respectively. From this point, it would in principle be possible to derive the subsequent differentiability results for the control-to-state mapping by using the implicit function theorem. A corresponding approach was taken in Chapter 5 in [16] for the case of standard Neumann boundary conditions not involving dynamic terms or the surface Laplacian. Here, we prefer a direct approach which, while being slightly longer and possibly less elegant than the use of the implicit function theorem, has the advantage of yielding the explicit form of the corresponding derivatives directly.

With Lemma 2.3 at hand, we are now able to improve the stability estimate (2.8) from Theorem 2.1.

\textbf{Lemma 2.4} Suppose that the general assumptions (A2)–(A5) are satisfied. Then there is a constant \( K_3^* > 0 \), which only depends on \( \Omega, T, f, g, \) and \( R \), such that the following holds: whenever \((u_1, u_{1r}), (u_2, u_{2r}) \in U\) are given and \((y_1, y_{1r}), (y_2, y_{2r}) \in Y\) are the associated solutions to the state system (1.2)–(1.4), then we have

\[
\|(y_1, y_{1r}) - (y_2, y_{2r})\|_Y \leq K_3^* \|(u_1, u_{1r}) - (u_2, u_{2r})\|_U.
\]

\textbf{Proof:} In the following, we denote by \( C_i, i \in \mathbb{N}, \) positive constants that only depend on the quantities mentioned in the assertion. We subtract the state equations (1.2)–(1.4) corresponding to \(((u_i, u_{ir}), (y_i, y_{ir})), i = 1, 2,\) from each other and multiply the equation resulting from (1.2) by \( \partial_t(y_1 - y_2) \). Putting \( u = u_1 - u_2, u_{1r} = u_{1r} - u_{2r}, y = y_1 - y_2, \) and \( y_{1r} = y_{1r} - y_{2r}, \) we have for all \( t \in [0, T] \) the estimate

\[
\int_0^t \int_\Omega \gamma^2 \, dx \, ds + \frac{1}{2} \int_\Omega |\nabla \gamma(t)|^2 \, dx + \int_0^t \int_\Gamma |\partial_t y_{1r}|^2 \, d\Gamma \, ds + \frac{1}{2} \int_\Gamma |\nabla y_{1r}(t)|^2 \, d\Gamma \\
\leq \int_0^t \int_\Omega |f'(y_1) - f'(y_2)| \, \gamma \, dx \, ds + \int_0^t \int_\Gamma |g'(y_{1r}) - g'(y_{2r})| \, |\partial_t y_{1r}| \, d\Gamma \, ds \\
+ \int_0^t \int_\Omega |u| \, y_{1r} \, dx \, ds + \int_0^t \int_\Gamma |u_{1r}| \, |\partial_t y_{1r}| \, d\Gamma \, ds.
\]

Now observe that Lemma 2.3 (see also (2.29)) and the mean value theorem imply that there is some constant \( C_i > 0 \) such that

\[
|f'(y_1) - f'(y_2)| \leq C_i |y| \quad \text{a.e. in } Q, \quad |g'(y_{1r}) - g'(y_{2r})| \leq C_i |y_{1r}| \quad \text{a.e. in } \Sigma.
\]
Hence, it follows from Young’s inequality and (2.8) that

\[
\|y\|_{H^1(0,T;H)} + \|y\|_{H^1(0,T;V)} \leq C_2 \|(u,u_T)\|_H. \tag{2.32}
\]

From this point we may continue as in the proof of Theorem 2.2 after proving the estimate (2.15): indeed, by the arguments used there, we can repeat the estimates (2.16) to (2.21) with \((w,w_T)\) replaced by \((y,y_T)\) to come to the conclusion that (2.30) is satisfied. This concludes the proof of the assertion.

3 The optimal control problem

We now consider the optimal control problem \((CP)\) under the general assumptions \((A1)–(A4)\).

3.1 Existence

We have the following existence result.

**Theorem 3.1** Suppose that the general assumptions \((A1)–(A4)\) are fulfilled. Then the optimal control problem \((CP)\) admits a solution.

**Proof:** Let \(\{u_n, u_{nT}\} \subset U_{ad}\) be a minimizing sequence for \((CP)\), and let \((y_n,y_{nT}) = S(u_n,u_{nT})\), \(n \in \mathbb{N}\). By virtue of the global estimates (2.6) and (2.24), we may assume (by possibly selecting a suitable subsequence again indexed by \(n\)) that there are functions \((\bar{u}, \bar{u}_\Gamma) \in \mathcal{X}\) and \((\bar{y}, \bar{y}_\Gamma) \in \mathcal{Y}\), such that

- \(u_n \rightharpoonup u\) weakly-* in \(L^\infty(Q)\),
- \(u_{nT} \rightharpoonup u_{\Gamma}\) weakly-* in \(L^\infty(\Sigma)\),
- \(y_n \rightharpoonup y\) weakly-* in \(H^1(0,T;H) \cap L^\infty(0,T;V) \cap L^2(0,T;H^2(\Omega)) \cap L^\infty(Q)\),
- \(y_{nT} \rightharpoonup y_{\Gamma}\) weakly-* in \(H^1(0,T;H_\Gamma) \cap L^\infty(0,T;V_\Gamma) \cap L^2(0,T;H^2(\Gamma)) \cap L^\infty(\Sigma)\).

In particular, we have

\[
\partial_n y_n \rightharpoonup \partial_n \bar{y}, \quad \Delta_\Gamma y_{nT} \rightharpoonup \Delta_\Gamma \bar{y}_\Gamma, \quad \text{both weakly in } L^2(\Sigma).
\]

Clearly, \((\bar{u}, \bar{u}_\Gamma) \in U_{ad}\). Moreover, we infer from standard compact embedding results (cf. [15, Sect. 8, Cor. 4] that, in particular,

\[
y_n \rightarrow \bar{y} \quad \text{strongly in } C^0([0,T]; H), \tag{3.1}
\]

\[
y_{nT} \rightarrow \bar{y}_\Gamma \quad \text{strongly in } C^0([0,T]; H_\Gamma). \tag{3.2}
\]

But then we can conclude from the Lipschitz continuity of \(f_2'\) and \(g_2'\) (see (A2)) that also

\[
f_2'(y_n) \rightarrow f_2'(\bar{y}) \quad \text{strongly in } C^0([0,T]; H),
\]

\[
g_2'(y_{nT}) \rightarrow g_2'(\bar{y}_\Gamma) \quad \text{strongly in } C^0([0,T]; H_\Gamma),
\]
while (2.7) and (A2) allow us to deduce that

\[
    f'_1(y_n) \to \xi \quad \text{weakly in } L^2(0, T; H),
\]
\[
    g'_1(y_n) \to \xi_{\Gamma} \quad \text{weakly in } L^2(0, T; H_{\Gamma}).
\]

for some weak limits \( \xi \) and \( \xi_{\Gamma} \). Since \( f_1 \) and \( g_1 \) are convex (so that \( f'_1 \) and \( g'_1 \) are increasing), the weak convergences above, along with (3.1)–(3.2), imply that \( \xi = f'_1(\bar{y}) \) a.e. in \( Q \) and \( \xi_{\Gamma} = g'_1(\bar{y}_{\Gamma}) \) a.e. on \( \Sigma \), due to the maximal monotonicity of the operators induced by \( f'_1 \) on \( L^2(Q) \) and \( g'_1 \) on \( L^2(\Sigma) \) (see, e.g., [1, Prop. 2.5, p. 27]). At this point, we may pass to the limit as \( n \to \infty \) in the state system (1.2)–(1.4) (written for \( (y_n, u_n, u_{\Gamma}) \), \( n \in \mathbb{N} \)) to conclude that \((\bar{y}, \bar{y}_{\Gamma}) = S(\bar{u}, \bar{u}_{\Gamma}) \), that is, the pair \(((\bar{u}, \bar{u}_{\Gamma}), (\bar{y}, \bar{y}_{\Gamma}))\) is admissible for (CP). It then follows from the lower sequential semicontinuity of the cost functional \( J \) that \((\bar{u}, \bar{u}_{\Gamma})\) is in fact an optimal control for (CP).

3.2 Differentiability of the control-to-state operator

Suppose now that \((\bar{u}, \bar{u}_{\Gamma}) \in \mathcal{U}_{ad}\) is a local minimizer for (CP), and let \((\bar{y}, \bar{y}_{\Gamma}) = S(\bar{u}, \bar{u}_{\Gamma})\) be the associated state. We consider for fixed \((h, h_{\Gamma}) \in \mathcal{X}\) the linearized system:

\[
    \xi_t - \Delta \xi + f''(\bar{y}) \xi = h \quad \text{a.e. in } Q, \quad (3.3)
\]
\[
    \partial_n \xi + \partial_t \xi_{\Gamma} - \Delta_{\Gamma} \xi_{\Gamma} + g''(\bar{y}_{\Gamma}) \xi_{\Gamma} = h_{\Gamma}, \quad \xi_{\Gamma} = \xi_{\Gamma}, \quad \text{a.e. on } \Sigma, \quad (3.4)
\]
\[
    \xi(\cdot, 0) = 0 \quad \text{a.e. in } \Omega, \quad \xi_{\Gamma}(\cdot, 0) = 0 \quad \text{a.e. on } \Gamma. \quad (3.5)
\]

By Theorem 2.2 the system (3.3)–(3.5) admits for every \((h, h_{\Gamma}) \in \mathcal{H}\) (and thus, a fortiori, for every \((h, h_{\Gamma}) \in \mathcal{X}\)) a unique solution \((\xi, \xi_{\Gamma}) \in \mathcal{Y}\), and the linear mapping \((h, h_{\Gamma}) \mapsto (\xi, \xi_{\Gamma})\) is continuous from \(\mathcal{H}\) into \(\mathcal{Y}\) and thus also from \(\mathcal{X}\) into \(\mathcal{Y}\).

We have the following differentiability result.

**Theorem 3.2** Suppose that the assumptions (A2)–(A5) are satisfied. Then we have the following results:

(i) Let \((\bar{u}, \bar{u}_{\Gamma}) \in \mathcal{U}\) be arbitrary. Then the control-to-state mapping \(S\), viewed as a mapping from \(\mathcal{X}\) into \(\mathcal{Y}\), is Fréchet differentiable at \((\bar{u}, \bar{u}_{\Gamma})\), and the Fréchet derivative \(DS(\bar{u}, \bar{u}_{\Gamma})\) is given by \(DS(\bar{u}, \bar{u}_{\Gamma})(\bar{h}, h_{\Gamma}) = (\xi, \xi_{\Gamma})\), where for any given \((h, h_{\Gamma}) \in \mathcal{X}\) the pair \((\xi, \xi_{\Gamma})\) denotes the solution to the linearized system (3.3)–(3.5).

(ii) The mapping \(DS : \mathcal{U} \to \mathcal{L}(\mathcal{X}, \mathcal{Y}), (\bar{u}, \bar{u}_{\Gamma}) \mapsto DS(\bar{u}, \bar{u}_{\Gamma})\) is Lipschitz continuous on \(\mathcal{U}\) in the following sense: there is a constant \(K^*_4 > 0\) such that for all \((u, u_{\Gamma}), (\bar{u}, \bar{u}_{\Gamma}) \in \mathcal{U}\) and all \((h, h_{\Gamma}) \in \mathcal{X}\) it holds

\[
    ||(DS(u, u_{\Gamma}) - DS(\bar{u}, \bar{u}_{\Gamma}))(h, h_{\Gamma})||_Y \leq K^*_4 \|(u, u_{\Gamma}) - (\bar{u}, \bar{u}_{\Gamma})\|_H \|(h, h_{\Gamma})\|_H. \quad (3.6)
\]

**Proof:** We first show (i). To this end, let \((\bar{u}, \bar{u}_{\Gamma}) \in \mathcal{U}\) be arbitrarily chosen, and let \((\bar{y}, \bar{y}_{\Gamma}) = S(\bar{u}, \bar{u}_{\Gamma}) \in \mathcal{Y}\) denote the associated solution to the state system. Since \(\mathcal{U}\) is an open subset of \(\mathcal{X}\), there is some \(\lambda > 0\) such that for any \((h, h_{\Gamma}) \in \mathcal{X}\) with \(\|(h, h_{\Gamma})\|_\mathcal{X} \leq \lambda\) it holds \((\bar{u}, \bar{u}_{\Gamma}) + (h, h_{\Gamma}) \in \mathcal{U}\). In the following, we consider such variations \((h, h_{\Gamma}) \in \mathcal{X}\), and we denote by \((y^h, y^h_{\Gamma})\) the solution to the state system (1.2)–(1.4) associated with \((\bar{u}, \bar{u}_{\Gamma}) + (h, h_{\Gamma})\). Moreover, we denote
by \((\xi^h, \xi_T^h)\) the unique solution to the linearized system (3.3)–(3.5) associated with \((h, h_T)\). We also denote by \(C_i, i \in \mathbb{N}\), positive constants that depend neither on the choice of \((h, h_T) \in \mathcal{X}\) with 
\[
\| (h, h_T) \|_{\mathcal{X}} \leq \lambda \text{ nor on } t \in [0, T].
\]

Now let 
\[
v^h := y^h - \bar{y} - \xi^h, \quad v_t^h := y_t^h - \bar{y}_t - \xi_t^h.
\]

Obviously, we have \((v^h, v_t^h) \in \mathcal{Y}\). Since the linear mapping \((h, h_T) \mapsto (\xi^h, \xi_T^h)\) is by Theorem 2.2 (ii) continuous from \(\mathcal{X}\) into \(\mathcal{Y}\), it obviously suffices to show that there is an increasing function \(G : [0, \lambda] \to [0, +\infty)\) which satisfies 
\[
\lim_{r \to 0} G(r) / r = 0 \quad \text{and}
\]
\[
\| (v^h, v_t^h) \|_\mathcal{Y} \leq G \left( \| (h, h_T) \|_{\mathcal{H}} \right).
\]  

(3.7)

Apparently, \(v^h\) is a solution to the initial-boundary value problem

\[
v_t^h - \Delta v^h + f'(y^h) - f'(\bar{y}) - f''(\bar{y}) \xi^h = 0 \quad \text{a.e. in } Q,
\]

\[
\partial_n v^h + \partial_t v_t^h - \Delta_T v_t^h + g'(y^h) - g'(\bar{y}) - g''(\bar{y}) \xi_t^h = 0 \quad \text{a.e. on } \Sigma, \tag{3.8}
\]

\[
v^h(\cdot, 0) = 0 \quad \text{a.e. in } \Omega \quad v_t^h(\cdot, 0) = 0 \quad \text{a.e. on } \Gamma. \tag{3.9}
\]

Next, we observe that it follows from Taylor’s theorem and from the global estimate (2.24) (cf. also (2.29)) that almost everywhere on \(Q\) we have

\[
f'(y^h) - f'(\bar{y}) - f''(\bar{y}) \xi^h = f''(\bar{y}) v^h + \Phi^h, \tag{3.10}
\]

where

\[
\| \Phi^h \|_{L^\infty(Q)} \leq \frac{1}{2} \max_{r^* \leq r \leq r^*} \max_{q^* \leq q \leq q^*} \max_{t^* \leq t \leq t^*} \| f'''(r) \| \| g^h - \bar{y} \|^2 \leq \frac{K^*}{2} \| y^h - \bar{y} \|^2.
\]  

(3.11)

By the same token, there is a function \(\Phi_T \in L^\infty(\Sigma)\) such that, almost everywhere on \(\Sigma\),

\[
g'(y^h) - g'(\bar{y}_T) - g''(\bar{y}_T) \xi^h_T = g''(\bar{y}_T) v_t^h + \Phi_T^h, \tag{3.12}
\]

where

\[
\| \Phi_T^h \|_{L^\infty(\Sigma)} \leq \frac{K^*}{2} \| y^h - \bar{y}_T \|^2.
\]  

(3.13)

Hence, with \(c_1 := f''(\bar{y}) \in L^\infty(Q)\), \(c_2 := g''(\bar{y}_T) \in L^\infty(\Sigma)\), \(u := -\Phi^h \in L^2(Q)\), and \(u_T := -\Phi_T^h \in L^2(\Sigma)\), we see that the system (3.8)–(3.10) satisfied by \((v^h, v_t^h)\) has exactly the structure of the system (2.9)–(2.11). It therefore follows from (2.12) in Theorem 2.2 that

\[
\| (v^h, v_t^h) \|_{\mathcal{Y}} \leq C_1 \| (\Phi^h, \Phi_T^h) \|_{\mathcal{H}}.
\]  

(3.14)

Now observe that, owing to the embedding \(V \subset L^4(\Omega)\) and to (2.30) in Lemma 2.4, we have

\[
\| \Phi^h \|_{L^2(Q)}^2 \leq C_2 \int_0^T \int_{\Omega} |y^h - \bar{y}|^4 \, dx \, dt = C_2 \int_0^T \| y^h(t) - \bar{y}(t) \|_{L^4(\Omega)}^4 \, dt \leq C_2 T \| y^h - \bar{y} \|_{C^0([0, T]; V)}^4 \leq C_3 \| (h, h_T) \|_{\mathcal{H}}^4.
\]  

(3.15)
Similar reasoning shows that also
\[ \| \Phi_k^h \|^2_{L^2(\Sigma)} \leq C_4 \|(h, h_\Gamma)\|^4_{\mathcal{H}}. \]

In conclusion, (3.7) is satisfied for the function \( G(r) = C_1(\sqrt{C_3} + \sqrt{C_4}) r^2 \), which concludes the proof of assertion (i).

Next, we show the validity of (ii). To this end, let \((\bar{u}, \bar{u}_\Gamma) \in \mathcal{U}\) be arbitrary, and let \((k, k_\Gamma) \in \mathcal{X}\) be such that \((\bar{u} + k, \bar{u}_\Gamma + k_\Gamma) \in \mathcal{U}\). We denote \((y_k^k, y_k^{k_\Gamma}) = S(\bar{u} + k, \bar{u}_\Gamma + k_\Gamma)\) and \((\bar{y}, \bar{y}_\Gamma) = S(\bar{u}, \bar{u}_\Gamma)\), and we assume that any \((h, h_\Gamma) \in \mathcal{X}\) with \(\|(h, h_\Gamma)\|_{\mathcal{X}} = 1\) is given. It then suffices to show that there is some \(L > 0\), independent of \((h, h_\Gamma)\), \((\bar{u}, \bar{u}_\Gamma)\) and \((k, k_\Gamma)\), such that
\[ \|(\xi_k^k, \xi_k^{k_\Gamma}) - (\xi, \xi_\Gamma)\|_{\mathcal{Y}} \leq L \|(k, k_\Gamma)\|_{\mathcal{H}}, \tag{3.17} \]
where \((\xi_k^k, \xi_k^{k_\Gamma}) = DS(\bar{u} + k, \bar{u}_\Gamma + k_\Gamma)(h, h_\Gamma)\) and \((\xi, \xi_\Gamma) = DS(\bar{u}, \bar{u}_\Gamma)(h, h_\Gamma)\). For this purpose, we denote in the following by \(K_i, i \in \mathbb{N}\), positive constants that neither depend on \((\bar{u}, \bar{u}_\Gamma)\), \((k, k_\Gamma)\), nor on the special choice of \((h, h_\Gamma) \in \mathcal{X}\) with \(\|(h, h_\Gamma)\|_{\mathcal{X}} = 1\).

To begin with, observe that from part (i) it easily follows that \((w, w_\Gamma) := (\xi_k^k, \xi_k^{k_\Gamma}) - (\xi, \xi_\Gamma) \in \mathcal{Y}\) solves the initial-boundary value problem
\[ w_t - \Delta w + f''(\bar{y}) w = -\xi_k^k f''(y_k^k) - f''(\bar{y}) \quad \text{a.e. in } Q, \tag{3.18} \]
\[ \partial_n w + \partial_\lambda w - \Delta_\lambda w_\Gamma + g''(\bar{y}_\Gamma) w_\Gamma = -\xi_k^{k_\Gamma} g''(y_k^{k_\Gamma}) - g''(\bar{y}_\Gamma) \quad \text{a.e. on } \Sigma, \tag{3.19} \]
\[ w(\cdot, 0) = 0 \quad \text{a.e. in } \Omega, \quad w_\Gamma(\cdot, 0) = 0 \quad \text{a.e. on } \Gamma. \tag{3.20} \]

Hence, it follows from Theorem 2.2 that
\[ \|(w, w_\Gamma)\|_{\mathcal{Y}} \leq K_1 \left( \|\xi_k^k f''(y_k^k) - f''(\bar{y})\|_{L^2(Q)} + \|\xi_k^{k_\Gamma} g''(y_k^{k_\Gamma}) - g''(\bar{y}_\Gamma)\|_{L^2(\Sigma)} \right). \tag{3.21} \]

Now, by Taylor’s theorem and (2.29), we have almost everywhere in \(Q\) (on \(\Sigma\), respectively)
\[ |f''(y_k^k) - f''(\bar{y})| \leq K_1^* |y_k^k - \bar{y}| \quad \text{and} \quad |g''(y_k^{k_\Gamma}) - g''(\bar{y}_\Gamma)| \leq K_1^* |y_k^{k_\Gamma} - \bar{y}_\Gamma|. \tag{3.22} \]

At this point, we recall that \(\mathcal{U}\) is obviously a bounded subset of \(\mathcal{H}\). Since \((\bar{u} + k, \bar{u} + k_\Gamma) \in \mathcal{U}\) and \(\|(h, h_\Gamma)\|_{\mathcal{X}} = 1\), we thus can infer from (2.29) and from the estimate (2.12) in Theorem 2.2 that \((\xi_k^k, \xi_k^{k_\Gamma})\) is bounded in \(\mathcal{Y}\) independently of \((k, k_\Gamma)\), \((\bar{u}, \bar{u}_\Gamma)\), and the choice of \((h, h_\Gamma) \in \mathcal{X}\) with \(\|(h, h_\Gamma)\|_{\mathcal{X}} = 1\). Using the embedding \(V \subset L^4(\Omega)\) and Lemma 2.4, we therefore have
\[
\|\xi_k^k (f''(y_k^k) - f''(\bar{y}))\|^2_{L^2(Q)} \leq K_2 \int_0^T \int_\Omega |\xi_k^k|^2 |y_k^k - \bar{y}|^2 \, dx \, dt \\
\leq K_2 \int_0^T \|\xi_k^k(t)\|^2_{L^4(\Omega)} \|y_k^k(t) - \bar{y}(t)\|^2_{L^4(\Omega)} \, dt \\
\leq K_3 \|(y_k^k - \bar{y}, y_k^{k_\Gamma} - \bar{y}_\Gamma)\|^2_{\mathcal{Y}} \leq K_4 \|(k, k_\Gamma)\|^2_{\mathcal{H}}. \tag{3.23} \]

Since an analogous estimate holds for the second summand in the bracket on the right-hand side of (3.21), the assertion follows. \(\blacksquare\)
Remark 5: Notice that we could not establish Fréchet differentiability of $S$ on $\mathcal{H}$; in fact, we only were able to show differentiability on the bounded subset $\mathcal{U}$ of $\mathcal{X}$. In particular, the boundedness of $(u, u_\Gamma)$ in $\mathcal{X}$ was an indispensable prerequisite for proving Lemma 2.3 and the global estimate (2.29), which in turn was fundamental for the derivation of the differentiability result. This will below lead to a so-called two-norm discrepancy in the derivation of second-order sufficient optimality conditions, i.e., we will have to work with two different norms.

With Theorem 3.2 at hand, it is now straightforward to derive the standard variational inequality that optimal controls must satisfy: indeed, it follows from the quadratic form of $J$ and from the chain rule that the reduced cost functional

$$J(u, u_\Gamma) := J(S(u, u_\Gamma), (u, u_\Gamma))$$

(3.24)

is Fréchet differentiable at every $(\bar{u}, \bar{u}_\Gamma) \in \mathcal{U}$ with the Fréchet derivative

$$DJ(\bar{u}, \bar{u}_\Gamma) = DJ(y, y_\Gamma) \circ DS(\bar{u}, \bar{u}_\Gamma) + DJ(u, u_\Gamma) \circ DS(\bar{u}, \bar{u}_\Gamma),$$

(3.25)

and, owing to the convexity of $\mathcal{U}_{ad}$, we have for every minimizer $(\bar{u}, \bar{u}_\Gamma) \in \mathcal{U}_{ad}$ of $J$ in $\mathcal{U}_{ad}$ that

$$DJ(\bar{u}, \bar{u}_\Gamma) (v - \bar{u}, v_\Gamma - \bar{u}_\Gamma) \geq 0 \quad \forall (v, v_\Gamma) \in \mathcal{U}_{ad}.$$  

(3.26)

Identification of the expressions in (3.25) from (1.1) and Theorem 3.2 yields the following result:

**Corollary 3.3** Let the assumptions (A1)–(A5) be satisfied, and let $(\bar{u}, \bar{u}_\Gamma) \in \mathcal{U}_{ad}$ be an optimal control for the control problem (CP) with associated state $(\bar{y}, \bar{y}_\Gamma) = S(\bar{u}, \bar{u}_\Gamma) \in \mathcal{Y}$. Then we have for every $(v, v_\Gamma) \in \mathcal{U}_{ad}$

$$\beta_1 \int_0^T \int_\Omega (\bar{y} - z_Q) \xi \, dx \, dt + \beta_2 \int_0^T \int_\Gamma (\bar{y}_\Gamma - z_{\Sigma}) \xi_\Gamma \, d\Gamma \, dt$$

$$+ \beta_3 \int_\Omega (\bar{y}(\cdot, T) - z_T) \xi(\cdot, T) \, dx + \beta_4 \int_\Gamma (\bar{y}_\Gamma(\cdot, T) - z_{\Gamma,T}) \xi_\Gamma(\cdot, T) \, d\Gamma$$

$$+ \beta_5 \int_0^t \int_\Omega (v - \bar{u}) \, dx \, dt + \beta_6 \int_0^t \int_\Gamma (v_\Gamma - \bar{u}_\Gamma) \, d\Gamma \, dt \geq 0,$$  

(3.27)

where $(\xi, \xi_\Gamma) \in \mathcal{Y}$ is the unique solution to the linearized system (3.3)–(3.5) associated with $(h, h_\Gamma) = (v - \bar{u}, v_\Gamma - \bar{u}_\Gamma)$.

### 3.3 First-order necessary optimality conditions

We are now in the position to derive the first-order necessary optimality conditions for the control problem (CP).

**Theorem 3.4** Let the assumptions (A1)–(A5) be satisfied, and let $(\bar{u}, \bar{u}_\Gamma) \in \mathcal{U}_{ad}$ be an optimal control for the control problem (CP) with associated state $(\bar{y}, \bar{y}_\Gamma) = S(\bar{u}, \bar{u}_\Gamma) \in \mathcal{Y}$. Then the adjoint
state system

\[-p_t - \Delta p + f''(\bar{y}) p = \beta_1 (\bar{y} - z_Q) \quad \text{a.e. in } Q, \tag{3.28}\]

\[\partial_n p - \partial_t p_{\Gamma} - \Delta_{\Gamma} p_{\Gamma} + g''(\bar{y}_{\Gamma}) p_{\Gamma} = \beta_2 (\bar{y}_{\Gamma} - z_\Sigma) \quad \text{a.e. on } \Sigma, \tag{3.29}\]

\[p(\cdot, T) = \beta_3 (\bar{y}(\cdot, T) - z_T) \quad \text{a.e. in } \Omega,\]

\[p_{\Gamma}(\cdot, T) = \beta_4 (\bar{y}_{\Gamma}(\cdot, T) - z_{\Gamma,T}) \quad \text{a.e. on } \Gamma, \tag{3.30}\]

has a unique solution \((p, p_{\Gamma}) \in \mathcal{Y}, \text{ and for every } (v, v_{\Gamma}) \in \mathcal{U}_{\text{ad}} \text{ we have}\]

\[
\int_0^T \int_{\Omega} (p + \beta_5 \bar{u})(v - \bar{u}) \, dx \, dt + \int_0^T \int_{\Gamma} (p_{\Gamma} + \beta_6 \bar{u}_{\Gamma})(v_{\Gamma} - \bar{u}_{\Gamma}) \, d\Gamma \, dt \geq 0. \tag{3.31}\]

**Proof:** First observe that the system (3.28)–(3.30) is a linear backward-in-time parabolic initial-boundary value problem, which after the time transformation \(t \mapsto T - t\) takes the form of the system (2.9)–(2.11) provided we put

\[c_1(x, t) := f''(\bar{y}(x, T - t)), \quad c_2(x, t) := g''(\bar{y}_{\Gamma}(x, T - t)),\]

\[u(x, t) := \beta_1 (\bar{y} - z_Q)(x, T - t), \quad u_{\Gamma}(x, t) := \beta_2 (\bar{y}_{\Gamma} - z_\Sigma)(x, T - t),\]

\[w_0(x) := \beta_3 (\bar{y}(x, T) - z_T(x)), \quad w_{\Gamma}(x) := \beta_4 (\bar{y}_{\Gamma}(x, T) - z_{\Gamma,T}(x)).\]

Obviously, \(c_1 \in L^\infty(Q), \ c_2 \in L^\infty(\Sigma), \ u \in L^2(Q), \ u_{\Gamma} \in L^2(\Sigma), \ w_0 \in H^1(\Omega), \) and \(w_{\Gamma} \in H^1(\Gamma).\) Hence, by virtue of Theorem 2.2, the transformed system admits a unique solution \((w, w_{\Gamma}) \in \mathcal{Y}, \) so that \((p, p_{\Gamma})(x, t) := (w, w_{\Gamma})(x, T - t)\) is the unique solution to the adjoint system, and \((p, p_{\Gamma}) \in \mathcal{Y}.\)

At this point, we may perform the standard calculation, using repeated integration by parts and the systems (3.3)–(3.5) and (3.28)–(3.30), which shows that

\[
\beta_1 \int_0^T \int_{\Omega} (\bar{y} - z_Q) \xi \, dx \, dt + \beta_2 \int_0^T \int_{\Gamma} (\bar{y}_{\Gamma} - z_\Sigma) \xi_{\Gamma} \, d\Gamma \, dt
\]

\[
+ \beta_3 \int_{\Omega} (\bar{y}(\cdot, T) - z_T) \xi(\cdot, T) \, dx + \beta_4 \int_{\Gamma} (\bar{y}_{\Gamma}(\cdot, T) - z_{\Gamma,T}) \xi_{\Gamma}(\cdot, T) \, d\Gamma
\]

\[
= \int_0^T \int_{\Omega} p h \, dx \, dt + \int_0^T \int_{\Gamma} p_{\Gamma} h_{\Gamma} \, d\Gamma \, dt, \tag{3.32}\]

so that (3.31) follows from (3.27).

**Remark 6:** (i) It follows from the above considerations that the Fréchet derivative \(D\mathcal{J}(\bar{u}, \bar{u}_{\Gamma}) \in \mathcal{L}(\mathcal{X}, \mathcal{Y})\) can be identified with the pair \((p + \beta_5 \bar{u}, p_{\Gamma} + \beta_6 \bar{u}_{\Gamma})\) in the sense that, with the standard inner product \((\cdot, \cdot)_H\) in the Hilbert space \(H,\) we have

\[
D\mathcal{J}(\bar{u}, \bar{u}_{\Gamma})(h, h_{\Gamma}) = ((p + \beta_5 \bar{u}, p_{\Gamma} + \beta_6 \bar{u}_{\Gamma}), (h, h_{\Gamma}))_H \quad \forall (h, h_{\Gamma}) \in \mathcal{X}. \tag{3.33}\]
If $\beta_5 > 0$ and $\beta_6 > 0$ then it follows from standard arguments that the condition (3.31) can be given a pointwise interpretation in the following sense: we have almost everywhere in $Q$ (on $\Sigma$, respectively) that

\[
\bar{u}(x, t) = \begin{cases} 
\tilde{u}_2(x, t) & \text{if } \tilde{u}_2(x, t) < -\beta_5^{-1} p(x, t) \\
-\beta_5^{-1} p(x, t) & \text{if } \tilde{u}_1(x, t) \leq -\beta_5^{-1} p(x, t) \leq \tilde{u}_2(x, t), \\
\tilde{u}_1(x, t) & \text{if } \tilde{u}_1(x, t) > -\beta_5^{-1} p(x, t) 
\end{cases} \tag{3.34}
\]

where $\tilde{u}_1, \tilde{u}_2, \tilde{u}_1^\Gamma, \tilde{u}_2^\Gamma$ represent the control constraints defined in (A1).

### 3.4 The second-order Fréchet derivative of the control-to-state operator

Since the control problem (CP) is nonconvex, the first-order necessary optimality conditions established in the previous section are not sufficient. However, it is of utmost importance, e.g., for the numerical solution of (CP), to derive sufficient optimality conditions. For this purpose, it is necessary to show that the control-to-state mapping is twice continuously Fréchet differentiable. We have the following result.

**Theorem 3.5** Assume that in addition to the general conditions (A1)–(A5) we have:

(A6) $f, g \in C^4(0, 1)$.

Then we have the following results:

(i) The control-to-state operator $\bar{S}$ is at any $(\bar{u}, \bar{u}^\Gamma) \in \bar{U}$ twice Fréchet differentiable, and the second Fréchet derivative $D^2\bar{S}(\bar{u}, \bar{u}^\Gamma) \in \mathcal{L}(\mathcal{X}, \mathcal{L}(\mathcal{X}, \mathcal{Y}))$ is defined as follows: if $(h, h^\Gamma), (k, k^\Gamma) \in \mathcal{X}$ are arbitrary, then $D^2\bar{S}(\bar{u}, \bar{u}^\Gamma)[(h, h^\Gamma), (k, k^\Gamma)] =: (\bar{\eta}, \bar{\eta}^\Gamma) \in \mathcal{Y}$ is the unique solution to the initial-boundary value problem

\[
\begin{align*}
\eta_t - \Delta \eta + f''(\bar{y}) \eta &= -f^{(3)}(\bar{y}) \phi \psi \quad \text{a.e in } Q, \tag{3.35} \\
\partial_n \eta + \partial_n \eta^\Gamma - \Delta \eta^\Gamma + g''(\bar{y}^\Gamma) \eta^\Gamma &= -g^{(3)}(\bar{y}^\Gamma) \phi^\Gamma \psi^\Gamma \quad \text{a.e on } \Sigma, \tag{3.36} \\
\eta(\cdot, 0) &= 0 \quad \text{a.e in } \Omega, \quad \eta^\Gamma(\cdot, 0) = 0 \quad \text{a.e on } \Gamma, \tag{3.37}
\end{align*}
\]

where we have put

\[
(\bar{y}, \bar{y}^\Gamma) = S(\bar{u}, \bar{u}^\Gamma), \quad (\phi, \phi^\Gamma) = DS(\bar{u}, \bar{u}^\Gamma)(h, h^\Gamma), \quad (\psi, \psi^\Gamma) = DS(\bar{u}, \bar{u}^\Gamma)(k, k^\Gamma). \tag{3.38}
\]

(ii) The mapping $D^2 S : \bar{U} \to \mathcal{L}(\mathcal{X}, \mathcal{L}(\mathcal{X}, \mathcal{Y})), (\bar{u}, \bar{u}^\Gamma) \mapsto D^2 S(\bar{u}, \bar{u}^\Gamma)$, is Lipschitz continuous on $\bar{U}$ in the following sense: there exists a constant $K_5^* > 0$ such that for every $(u, u^\Gamma), (\bar{u}, \bar{u}^\Gamma) \in \bar{U}$ and all $(h, h^\Gamma), (k, k^\Gamma) \in \mathcal{X}$ it holds

\[
\|D^2 S(u, u^\Gamma) - D^2 S(\bar{u}, \bar{u}^\Gamma)\|(h, h^\Gamma), (k, k^\Gamma)\| \leq K_5^* \|(u, u^\Gamma)\|_{\mathcal{H}} \|(h, h^\Gamma)\|_{\mathcal{H}} \|(k, k^\Gamma)\|_{\mathcal{H}}. \tag{3.39}
\]
Moreover, by (2.12) we have the estimate

\[ V \text{embedding depend on the quantities} \quad (\phi, \phi_T), (\psi, \psi_T) \in \mathcal{Y} \text{ defined as in (3.38). Then, with} \]

\[
c_1 := f''(\bar{y}) \in L^\infty(Q), \quad c_2 := g''(\bar{y}_T) \in L^\infty(\Sigma), \quad u := -f^{(3)}(\bar{y}) \phi \psi \in L^2(Q),
\]

\[
u_T := -g^{(3)}(\bar{y}_T) \phi_T \psi_T \in L^2(\Sigma),
\]

the system (3.35)–(3.37) takes the form (2.9)–(2.11) and thus enjoys a unique solution \((\eta, \eta_T) \in \mathcal{Y}\). Moreover, by (2.12) we have the estimate

\[
\|(\eta, \eta_T)\|_\mathcal{Y} \leq \tilde{C}_1 \left( \|f^{(3)}(\bar{y}) \phi \psi\|_{{L^2}(Q)} + \|g^{(3)}(\bar{y}_T) \phi_T \psi_T\|_{{L^2}(\Sigma)} \right).
\]

(3.40)

In the remainder of the proof of part (i), we denote by \(C_i, i \in \mathbb{N}\), positive constants that do not depend on the quantities \((h, h_T), (k, k_T)\), and \((\bar{u}, \bar{u}_T)\). Using (2.29) and (2.30), and invoking the embedding \(V \subset L^2(\Omega)\), we find that

\[
\|f^{(3)}(\bar{y}) \phi \psi\|_{{L^2}(Q)}^2 \leq K_1 \int_0^T \|\phi(t)\|_{{L^4}(\Omega)}^2 \|\psi(t)\|_{{L^4}(\Omega)}^2 \, dt \leq C_1 \int_0^T \|\phi(t)\|_{{L^4}(\Omega)} \|\psi(t)\|_{{L^4}(\Omega)} \, dt
\]

\[
\leq C_2 \|\phi\|_{{C^0([0,T];V)}^2} \|\psi\|_{{C^0([0,T];V)}^2} \leq C_3 \|(h, h_T)\|_\mathcal{H}^2 \|(k, k_T)\|_\mathcal{H}^2,
\]

(3.41)

where the validity of the last inequality can be seen as follows: by definition (recall (3.38)) \((\phi, \phi_T)\) is the unique solution to the linear problem (3.3)–(3.5) with zero initial conditions, and thus we can infer from Theorem 2.2 (see, in particular, (2.12)) that the unique solution to the linear problem (3.3)–(3.5) with zero initial conditions, and thus we can infer from Theorem 2.2 (see, in particular, (2.12)) that \(\|(\phi, \phi_T)\|_\mathcal{Y} \leq \tilde{C} \|(h, h_T)\|_\mathcal{H}\). By the same token, we conclude that \(\|(\psi, \psi_T)\|_\mathcal{Y} \leq \tilde{C} \|(k, k_T)\|_\mathcal{H}\). The asserted inequality therefore follows from the definition of the norm of the space \(\mathcal{Y}\), and we obtain from similar reasoning that also

\[
\|g^{(3)}(\bar{y}_T) \phi_T \psi_T\|_{{L^2}(\Sigma)} \leq C_4 \|(h, h_T)\|_\mathcal{H} \|(k, k_T)\|_\mathcal{H}.
\]

In particular, it follows that the bilinear mapping \(\mathcal{X} \times \mathcal{X} \hookrightarrow \mathcal{Y}, [(k, k_T), (h, h_T)] \mapsto (\eta, \eta_T)\), is continuous.

Now we prove the assertions concerning existence and form of the second Fréchet derivative. Since \(\mathcal{U}\) is open, there is some \(\lambda > 0\) such that \((\bar{u} + k, \bar{u}_T + k_T) \in \mathcal{U}\) whenever \(\|(k, k_T)\|_\mathcal{X} \leq \lambda\). In the following, we only consider such perturbations \((k, k_T) \in \mathcal{X}\). Then for \((y^k, \psi^k) = S(\bar{u} + k, \bar{u}_T + k_T)\) the global estimates (2.6), (2.29), (2.30) are satisfied. Without loss of generality, we may also assume that

\[
\max \left\{ \|f^{(4)}(y^k)\|_{{L^\infty}(Q)}, \|g^{(4)}(y_T^k)\|_{{L^\infty}(\Sigma)} \right\} \leq K^*_1 \quad \text{whenever } \|(k, k_T)\|_\mathcal{X} \leq \lambda.
\]

(3.42)

After these preparations, we observe that it suffices to show that

\[
\|DS(\bar{u} + k, \bar{u}_T + k_T) - DS(\bar{u}, \bar{u}_T) - D^2S(\bar{u}, \bar{u}_T)(k, k_T)\|_{{L(\mathcal{X}, \mathcal{Y})}}
\]

\[
= \sup_{\|(h, h_T)\|_\mathcal{X} = 1} \left\| \left( DS(\bar{u} + k, \bar{u}_T + k_T) - DS(\bar{u}, \bar{u}_T) - D^2S(\bar{u}, \bar{u}_T)(k, k_T) \right) (h, h_T) \right\|_\mathcal{Y}
\]

\[
\leq G \left( \|(k, k_T)\|_\mathcal{H} \right),
\]

(3.43)

with an increasing function \(G : [0, \lambda] \rightarrow (0, +\infty)\) that satisfies \(\lim_{r \downarrow 0} G(r)/r = 0\).
To this end, let \((h, h_\Gamma) \in \mathcal{X}\) be arbitrary with \(\|h\|_{L^\infty(Q)} + \|h_\Gamma\|_{L^\infty(\Sigma)} = 1\). We put \((\rho, \rho_\Gamma) = DS(\bar{u} + k, \bar{y}_\Gamma + k_\Gamma)(h, h_\Gamma)\), define the pairs \((\phi, \phi_\Gamma), (\psi, \psi_\Gamma) \in \mathcal{Y}\) as in (3.38), and put
\[
(w, w_\Gamma) := (\rho - \phi - \eta, \rho_\Gamma - \phi_\Gamma - \eta_\Gamma).
\]

Then, according to (3.43), we need to show that
\[
\|(w, w_\Gamma)\|_\mathcal{Y} \leq G (\|(k, k_\Gamma)\|_\mathcal{H}) .
\] (4.44)

Now, invoking the explicit expressions for the quantities defined above, it is easily seen that \((w, w_\Gamma)\) is a solution to the linear initial-boundary value problem
\[
w_t - \Delta w + f''(\bar{y}) w = \sigma \quad \text{a.e. in } Q, \tag{4.45}
\]
\[
\partial_n w + \partial_n w_\Gamma - \Delta_\Gamma w_\Gamma + g''(\bar{y}_\Gamma) w_\Gamma = \sigma_\Gamma \quad \text{a.e. in } \Sigma, \tag{4.46}
\]
\[
w(\cdot, 0) = 0 \quad \text{a.e. in } \Omega, \quad w_\Gamma(\cdot, 0) = 0 \quad \text{a.e. on } \Gamma, \tag{4.47}
\]
where we have put
\[
\sigma := -\rho \left(f''(y_k^*) - f''(\bar{y})\right) + f^{(3)}(\bar{y}) \phi \psi, \quad \sigma_\Gamma := -\rho_\Gamma \left(g''(y_k^*) - g''(\bar{y}_\Gamma)\right) + g^{(3)}(\bar{y}_\Gamma) \phi_\Gamma \psi_\Gamma. \tag{4.48}
\]

In view of (2.29), and since it is easily checked that \((\sigma, \sigma_\Gamma) \in \mathcal{H}\), we may again invoke the estimate (2.12) in Theorem 2.2 to conclude that (4.44) is satisfied if only
\[
\|(\sigma, \sigma_\Gamma)\|_\mathcal{H} \leq G (\|(k, k_\Gamma)\|_\mathcal{H}) . \tag{4.49}
\]

Applying Taylor’s theorem to \(f''\), and recalling (3.38), we readily see that there is a function \(\omega_f \in L^\infty(Q)\) such that
\[
f''(y_k^*) - f''(\bar{y}) = f^{(3)}(\bar{y}) (y_k^* - \bar{y} - \psi) + f^{(3)}(\bar{y}) \psi + \omega_f (y_k^* - \bar{y})^2 \quad \text{a.e. in } Q. \tag{4.50}
\]

Hence, we have that
\[
\sigma = -\rho f^{(3)}(\bar{y}) (y_k^* - \bar{y} - \psi) - \psi f^{(3)}(\bar{y}) (\rho - \phi) - \rho \omega_f (y_k^* - \bar{y})^2. \tag{4.51}
\]

Now recall that from the proofs of Fréchet differentiability and of the Lipschitz continuity of the Fréchet derivative (see, in particular, the estimates (3.6)–(3.16) and (3.17)–(3.23), respectively) it follows that
\[
\|(y_k^* - \bar{y} - \psi, y_k^* - \bar{y}_\Gamma - \psi_\Gamma)\|_\mathcal{Y} \leq C_1 \|(k, k_\Gamma)\|_\mathcal{H}^2, \tag{4.52}
\]
\[
\|(\rho - \phi, \rho_\Gamma - \phi_\Gamma)\|_\mathcal{Y} \leq C_2 \|(k, k_\Gamma)\|_\mathcal{H}. \tag{4.53}
\]

Moreover, we can infer from Lemma 2.4 that
\[
\|(y_k^* - \bar{y}, y_k^* - \bar{y}_\Gamma)\|_\mathcal{Y} \leq K^*_2 \|(k, k_\Gamma)\|_\mathcal{H}, \tag{4.54}
\]
and it follows from Theorem 2.2 that \(\rho\) is bounded in \(\mathcal{Y}\) by a positive constant that is independent of \((k, k_\Gamma), (h, h_\Gamma) \in \mathcal{X}\) with \(\|(k, k_\Gamma)\|_\mathcal{X} \leq \lambda\) and \(\|(h, h_\Gamma)\|_\mathcal{X} = 1\).
Finally, we conclude from Remark 3 that with a suitable constant $C_3 > 0$ it holds
\[
\| (\psi, \psi_T) \|_Y \leq C_3 \| (k, k_T) \|_H .
\] (3.54)

After these preparations, and invoking Hölder’s inequality and the embeddings $V \subset L^4(\Omega)$ and $V \subset L^6(\Omega)$, we can estimate as follows:
\[
\| \sigma \|^2_{L^2(Q)} \leq C_4 \int_0^T \int_\Omega \left( |\rho|^2 |y^k - \bar{y} - \psi|^2 + |\psi|^2 |\rho - \phi|^2 + |\rho|^2 |y^k - \bar{y}|^4 \right) \, dx \, dt \\
\leq C_4 \int_0^T \left( \| \rho(t) \|^2_{L^4(\Omega)} \| (y^k - \bar{y} - \psi)(t) \|^2_{L^4(\Omega)} + \| \psi(t) \|^2_{L^4(\Omega)} \| \rho(t) - \phi(t) \|^2_{L^4(\Omega)} \right) dt \\
+ C_4 \int_0^T \| \rho(t) \|^2_{L^6(\Omega)} \| y^k(t) - \bar{y}(t) \|^2_{L^6(\Omega)} dt \\
\leq C_5 \max_{0 \leq t \leq T} \left( \| \rho(t) \|^2_Y \| (y^k - \bar{y} - \psi)(t) \|^2_Y + \| \psi(t) \|^2_Y \| \rho(t) - \phi(t) \|^2_Y \\
+ \| \rho(t) \|^2_Y \| y^k(t) - \bar{y}(t) \|^2_Y \right) \\
\leq C_6 \|(k, k_T)\|^4_H .
\] (3.55)

By the same reasoning, a similar estimate can be derived for $\| \sigma_T \|^2_{L^2(\Sigma)}$, which concludes the proof of the assertion (i).

Next, we prove the assertion (ii). To this end, suppose that $(\bar{u}, \bar{u}_T) \in U$ and that $(h, h_T)$ and $(k, k_T)$ are arbitrarily chosen in $X$, and let $(\bar{\delta}, \bar{\delta}_T) \in X$ be arbitrary with $(\bar{u} + \bar{\delta}, \bar{u}_T + \bar{\delta}_T) \in X$. In the following, we will denote by $C_i, i \in \mathbb{N}$, positive constants that do not depend on any of these quantities. We put
\[
(y^\delta, y_T^\delta) = S(\bar{u} + \delta, \bar{u}_T + \delta_T), \quad (\bar{y}, \bar{y}_T) = S(\bar{u}, \bar{u}_T), \quad (\phi, \phi_T) = DS(\bar{u}, \bar{u}_T)(h, h_T), \\
(\psi, \psi_T) = DS(\bar{u}, \bar{u}_T)(k, k_T), \quad (\phi^\delta, \phi_T^\delta) = DS(\bar{u} + \delta, \bar{u}_T + \delta_T)(h, h_T), \\
(\psi^\delta, \psi_T^\delta) = DS(\bar{u} + \delta, \bar{u}_T + \delta_T)(k, k_T), \quad (\eta, \eta_T) = D^2S(\bar{u}, \bar{u}_T)((h, h_T), (k, k_T)) , \\
(\eta^\delta, \eta_T^\delta) = D^2S(\bar{u} + \delta, \bar{u}_T + \delta_T)((h, h_T), (k, k_T)) .
\]

From the previous results, in particular, (2.30) and (3.6), we can infer that there is a constant $C_1 > 0$ such that
\[
\| (\phi, \phi_T) \|_Y + \| (\phi^\delta, \phi_T^\delta) \|_Y \leq C_1 \| (h, h_T) \|_H , \\
\| (\psi, \psi_T) \|_Y + \| (\psi^\delta, \psi_T^\delta) \|_Y \leq C_1 \| (k, k_T) \|_H , \\
\| (\eta, \eta_T) \|_Y + \| (\eta^\delta, \eta_T^\delta) \|_Y \leq C_1 \| (h, h_T) \|_H \| (k, k_T) \|_H , \\
\| (y^\delta, y_T^\delta) - (\bar{y}, \bar{y}_T) \|_Y \leq C_1 \| (\delta, \delta_T) \|_H , \\
\| (\phi^\delta, \phi_T^\delta) - (\phi, \phi_T) \|_Y \leq C_1 \| (\delta, \delta_T) \|_H \| (h, h_T) \|_H , \\
\| (\psi^\delta, \psi_T^\delta) - (\psi, \psi_T) \|_Y \leq C_1 \| (\delta, \delta_T) \|_H \| (k, k_T) \|_H .
\] (3.56)
Now observe that \((w, w_\Gamma) = (\eta^\delta, \eta^\delta_\Gamma) - (\eta, \eta_\Gamma)\) satisfies the linear initial-boundary value problem of the type (2.9)--(2.11)

\[
\begin{align*}
w_t - \Delta w + f''(\bar{y}) w &= \sigma & \text{a.e. in } Q, \\
\partial_n w + \partial_t w_\Gamma - \Delta_\Gamma w_\Gamma + g''(\bar{y}_\Gamma) w_\Gamma &= \sigma_\Gamma & \text{a.e. on } \Sigma, \\
w(\cdot, 0) = 0 & \text{ a.e. in } \Omega, & w_\Gamma(\cdot, 0) = 0 & \text{ a.e. on } \Gamma,
\end{align*}
\]

where we have put

\[
\begin{align*}
\sigma &= -\eta^\delta(f''(y^\delta) - f''(\bar{y})) - (f^{(3)}(y^\delta) \phi^\delta \psi^\delta - f^{(3)}(\bar{y}) \phi \psi), \\
\sigma_\Gamma &= -\eta^\delta_\Gamma(g''(y^\delta_\Gamma) - g''(\bar{y}_\Gamma)) - (g^{(3)}(y^\delta_\Gamma) \phi^\delta_\Gamma \psi^\delta_\Gamma - g^{(3)}(\bar{y}_\Gamma) \phi_\Gamma \psi_\Gamma).
\end{align*}
\]

From Theorem 2.2 it follows that

\[
\|(w, w_\Gamma)\|_Y \leq \hat{C}\|(\sigma, \sigma_\Gamma)\|_H,
\]

so that it remains to show an estimate of the form

\[
\|(\sigma, \sigma_\Gamma)\|_H \leq C_2\|(\delta, \delta_\Gamma)\|_H\|(h, h_\Gamma)\|_H\|(k, k_\Gamma)\|_H.
\]

Moreover, we can infer from (2.30) and (3.6) that, almost everywhere in \(Q\),

\[
|\sigma| \leq K_1(|\eta^\delta| |y^\delta - \bar{y}| + |\phi^\delta| |\psi^\delta| |y^\delta - \bar{y}| + |\phi^\delta| |\psi^\delta - \psi| + |\psi| |\phi^\delta - \phi|).
\]

Hence, by (3.56), and using Hölder’s inequality and the embedding \(V \subset L^4(\Omega)\),

\[
\begin{align*}
\int_0^T \int_\Omega |\eta^\delta|^2 |y^\delta - \bar{y}|^2 \, dx \, dt &\leq \int_0^T \|\eta^\delta(t)\|^2_{L^4(\Omega)} \|(y^\delta - \bar{y})(t)\|_{L^4(\Omega)} \, dt \\
&\leq C_3 \|\eta^\delta\|^2_{L^2(0,T;V)} \|y^\delta - \bar{y}\|^2_{L^2(0,T;V)} \leq C_4 \|\delta, \delta_\Gamma\|_H^2 \|(h, h_\Gamma)\|_H^2 \|(k, k_\Gamma)\|_H^2.
\end{align*}
\]

Similar reasoning yields

\[
\|\phi^\delta(\psi^\delta - \psi)\|^2_{L^2(Q)} + \|\psi(\phi^\delta - \phi)\|^2_{L^2(Q)} \leq C_5 \|\delta, \delta_\Gamma\|_H^2 \|(h, h_\Gamma)\|_H^2 \|(k, k_\Gamma)\|_H^2.
\]

Moreover, we invoke (3.56), Hölder’s inequality, and the embeddings \(V \subset L^4(\Omega)\) and \(H^2(\Omega) \subset L^\infty(\Omega)\), to conclude that

\[
\begin{align*}
\int_0^T \int_\Omega |\phi^\delta|^2 |\psi^\delta|^2 |y^\delta - \bar{y}|^2 \, dx \, dt &\leq \int_0^T \|(y^\delta - \bar{y})(t)\|^2_{L^\infty(\Omega)} \|\phi^\delta(t)\|^2_{L^4(\Omega)} \|\psi^\delta(t)\|^2_{L^4(\Omega)} \, dt \\
&\leq C_6 \|\phi^\delta\|^2_{L^2(0,T;V)} \|\psi^\delta\|^2_{L^2(0,T;H^2(\Omega))} \|y^\delta - \bar{y}\|^2_{L^2(0,T;H^2(\Omega))} \\
&\leq C_7 \|\delta, \delta_\Gamma\|_H^2 \|(h, h_\Gamma)\|_H^2 \|(k, k_\Gamma)\|_H^2.
\end{align*}
\]

Finally, we can estimate \(\|\sigma_\Gamma\|_{L^2(\Sigma)}\) deriving estimates similar to (3.63)--(3.66), which proves the validity of the required estimate (3.62). With this, the assertion is completely proved.
3.5 Second-order sufficient optimality conditions

With Theorem 3.5 at hand, the road is paved to derive sufficient conditions for optimality. But, because the control-to-state operator \( S \) is not Fréchet differentiable on \( \mathcal{H} \), we are faced with the two-norm discrepancy, which makes it impossible to establish second-order sufficient optimality conditions by means of the same simple arguments as in the finite-dimensional case or, e.g., in the proof of Theorem 4.23 on page 231 in [16]. It will thus be necessary to tailor the conditions in such a way as to overcome the two-norm discrepancy. At the same time, for practical purposes the conditions should not be overly restrictive. For such an approach, we follow the lines of Chapter 5 in [16], here. Since many of the arguments developed here are rather similar to those employed in [16], we can afford to be sketchy and refer the reader to [16] for full details.

To begin with, the quadratic cost functional \( J \), viewed as a mapping on \( \mathcal{Y} \times \mathcal{U} \), is obviously twice continuously Fréchet differentiable on \( \mathcal{Y} \times \mathcal{U} \), and for any \(((\bar{y}, \bar{y}_T), (\bar{u}, \bar{u}_T)) \in \mathcal{Y} \times \mathcal{U} \) and any \(((v, v_T), (h, h_T)), ((w, w_T), (k, k_T)) \in \mathcal{Y} \times \mathcal{X} \) it holds

\[
D^2 J((\bar{y}, \bar{y}_T), (\bar{u}, \bar{u}_T))[((v, v_T), (h, h_T)), ((w, w_T), (k, k_T))] = \beta_1 \int_0^T \int_{\Omega} v \, w \, dx \, dt + \beta_2 \int_0^T \int_{\Gamma} v_T \, w_T \, d\Gamma \, dt + \beta_3 \int_\Omega v(T) \, w(T) \, dx
\]

\[
+ \beta_4 \int_\Gamma v_T(T) \, w_T(T) \, d\Gamma + \beta_5 \int_0^T \int_{\Omega} h \, k \, dx \, dt + \beta_6 \int_0^T \int_{\Gamma} h_T \, k_T \, d\Gamma \, dt. \tag{3.67}
\]

Hence, it follows from Theorem 3.5 and from the chain rule that the reduced cost functional \( \bar{J} \) is twice continuously Fréchet differentiable on \( \mathcal{U} \). Now let \((\bar{u}, \bar{u}_T) \in \mathcal{U}\) be fixed and \((h, h_T), (k, k_T) \in \mathcal{X}\) be arbitrary. In accordance with our previous notation, we put

\[
(\bar{y}, \bar{y}_T) = S(\bar{u}, \bar{u}_T), \quad (\phi, \phi_T) = DS(\bar{u}, \bar{u}_T)(h, h_T), \quad (\psi, \psi_T) = DS(\bar{u}, \bar{u}_T)(k, k_T),
\]

\[
(\eta, \eta_T) = D^2 S(\bar{u}, \bar{u}_T)[((h, h_T), (k, k_T)].
\]

Then a straightforward calculation resembling that carried out on page 241 in [16], using the chain rule as main tool, yields the equality

\[
D^2 \bar{J}(\bar{u}, \bar{u}_T)[(h, h_T), (k, k_T)] = D_{(y,y_T)} \bar{J}((\bar{y}, \bar{y}_T), (\bar{u}, \bar{u}_T))(\eta, \eta_T)
\]

\[
+ D^2 J((\bar{y}, \bar{y}_T), (\bar{u}, \bar{u}_T))[((\phi, \phi_T), (h, h_T)), ((\psi, \psi_T), (k, k_T))]. \tag{3.68}
\]

Now observe that the first summand of the right-hand side of (3.68) is equal to the expression

\[
\beta_1 \int_0^T \int_{\Omega} (\bar{y} - z_Q) \eta \, dx \, dt + \beta_2 \int_0^T \int_{\Gamma} (\bar{y}_T - z_\Sigma) \eta_T \, d\Gamma \, dt
\]

\[
+ \beta_3 \int_\Omega (\bar{y}(T) - z_T) \eta(T) \, dx + \beta_4 \int_\Gamma (\bar{y}_T(T) - z_{T,T}) \eta_T(T) \, d\Gamma \tag{3.69}
\]

and that \((\eta, \eta_T)\) solves a system of the form (3.3)–(3.5), with \( h \) replaced by \(-f^{(3)}(\bar{y})\phi\psi \in L^2(Q)\) and \( h_T \) replaced by \(-g^{(3)}(\bar{y}_T)\phi_T\psi_T \in L^2(\Sigma)\). Since the calculation leading to the identity (3.32) also works for right-hand sides in \( L^2(Q) \times L^2(\Sigma) \), we can infer that

\[
D_{(y,y_T)} \bar{J}((\bar{y}, \bar{y}_T), (\bar{u}, \bar{u}_T))(\eta, \eta_T)
\]

\[
= -\int_0^T \int_{\Omega} p f^{(3)}(\bar{y}) \phi \psi \, dx \, dt - \int_0^T \int_{\Gamma} p_T g^{(3)}(\bar{y}_T) \phi_T \psi_T \, d\Gamma \, dt, \tag{3.70}
\]
where \((p, p_r) \in \mathcal{Y}\) is the adjoint state associated with \(((\bar{y}, \bar{y}_r), (\bar{u}, \bar{u}_r))\). Summarizing, we have that it holds the representation formula

\[
D^2 \mathcal{J}(\bar{u}, \bar{u}_r)[(h, \tau h_r), (h, \tau h_r)] = \int_0^T \int_{\Omega} (\beta_1 - p \, f^{(3)}(\bar{y})) |\phi|^2 \, dx \, dt \\
+ \int_0^T \int_{\Gamma} (\beta_2 - p_r \, g^{(3)}(\bar{y}_r)) |\phi_r|^2 \, d\Gamma \, dt \\
+ \beta_3 \int_{\Omega} |\phi(T)|^2 \, dx + \beta_4 \int_{\Gamma} |\phi_r(T)|^2 \, d\Gamma \\
+ \beta_5 \|h\|_{L^2(Q)}^2 + \beta_6 \|h_r\|_{L^2(\Sigma)}^2. 
\]  
(3.71)

Equality (3.71) gives rise to hope that, under appropriate conditions, \(D^2 \mathcal{J}(\bar{u}, \bar{u}_r)\) might be a positive definite operator on a suitable subset of the space \(\mathcal{H}\). To formulate such a condition, assume that \((\bar{u}, \bar{u}_r) \in \mathcal{U}_{ad}\) is a given control with associated state \((\bar{y}, \bar{y}_r) = S(\bar{u}, \bar{u}_r) \in \mathcal{Y}\) and adjoint state \(p \in \mathcal{Y}\) satisfying (3.28)–(3.30). We then introduce for fixed \(\tau > 0\) the set of strongly active constraints for \((\bar{u}, \bar{u}_r)\) by

\[
A_{\tau}(\bar{u}, \bar{u}_r) := \{(x, t) \in Q : |p(x, t) + \beta_5 \, \bar{u}(x, t)| > \tau\} \\
\cup \{(x, t) \in \Sigma : |\tau p(x, t) + \beta_6 \, \bar{u}_r(x, t)| > \tau\}.
\]  
(3.72)

Apparently it follows from (3.31) that, depending on the signs of \(p(x, t) + \beta_5 \, \bar{u}(x, t)\) and of \(\tau p(x, t) + \beta_6 \, \bar{u}_r(x, t)\), the control values \(\bar{u}(x, t)\) and \(\bar{u}_r(x, t)\), respectively, attain one of the constraint values.

We now define the \(\tau\)-critical cone \(C_{\tau}(\bar{u}, \bar{u}_r)\) to be the set of all \((h, \tau h_r) \in \mathcal{X}\) such that

\[
\begin{align*}
0 &= \text{if } (x, t) \in A_{\tau}(\bar{u}, \bar{u}_r) \\
\geq 0 &= \text{if } \bar{u}(x, t) = \bar{u}_1(x, t) \text{ and } (x, t) \notin A_{\tau}(\bar{u}, \bar{u}_r) \\
\leq 0 &= \text{if } \bar{u}(x, t) = \bar{u}_2(x, t) \text{ and } (x, t) \notin A_{\tau}(\bar{u}, \bar{u}_r) \\
\geq 0 &= \text{if } \bar{u}_r(x, t) = \bar{u}_1(x, t) \text{ and } (x, t) \notin A_{\tau}(\bar{u}, \bar{u}_r) \\
\leq 0 &= \text{if } \bar{u}_r(x, t) = \bar{u}_2(x, t) \text{ and } (x, t) \notin A_{\tau}(\bar{u}, \bar{u}_r).
\end{align*}
\]  
(3.73)

After these preparations, we can formulate the second-order sufficient optimality condition as follows:

There exist constants \(\delta > 0\) and \(\tau > 0\) such that

\[
D^2 \mathcal{J}[(\bar{u}, \bar{u}_r)[(h, \tau h_r), (h, \tau h_r)] \geq \delta \|h\|_{\mathcal{H}}^2 \quad \forall (h, \tau h_r) \in C_{\tau}(\bar{u}, \bar{u}_r),
\]

where \(D^2 \mathcal{J}[(\bar{u}, \bar{u}_r)[(h, \tau h_r), (h, \tau h_r)]\) is given by (3.71) with \((\bar{y}, \bar{y}_r) = S(\bar{u}, \bar{u}_r),\)

\[
(\phi, \phi_r) = DS(\bar{u}, \bar{u}_r)(h, \tau h_r) \quad \text{and the associated adjoint state } (p, p_r).
\]  
(3.74)

The following result resembles Theorem 5.17 in [16].

**Theorem 3.6** Suppose that the assumptions (A1)–(A6) are satisfied, and assume that the triple \((\bar{u}, \bar{u}_r) \in \mathcal{U}_{ad}\), \((\bar{y}, \bar{y}_r) = S(\bar{u}, \bar{u}_r) \in \mathcal{Y}\) and \((p, p_r) \in \mathcal{Y}\) fulfills the first-order necessary optimality conditions (3.28)–(3.31). Moreover, assume that the condition (3.74) is fulfilled. Then there are
constants $\varepsilon > 0$ and $\sigma > 0$ such that

$$J(u, u_{\Gamma}) \geq J(\bar{u}, \bar{u}_{\Gamma}) + \sigma \|(u - \bar{u}, u_{\Gamma} - \bar{u}_{\Gamma})\|_H^2$$

whenever $(u, u_{\Gamma}) \in U_{ad}$ and $\|(u, u_{\Gamma}) - (\bar{u}, \bar{u}_{\Gamma})\|_X \leq \varepsilon$.

(3.75)

In particular, $(\bar{u}, \bar{u}_{\Gamma})$ is locally optimal in the sense of $X$.

Proof: The proof closely resembles that of Theorem 5.17 in [16], and therefore we can refer to [16]. We only indicate one argument that needs a bit more explanation. To this end, let $(u, u_{\Gamma}) \in U_{ad}$ be arbitrary. Since $J$ is twice continuously Fréchet differentiable in $U$, it follows from Taylor’s theorem with integral remainder (see, e.g., Theorem 8.14.3 on page 186 in [4]) that

$$J(u, u_{\Gamma}) - J(\bar{u}, \bar{u}_{\Gamma}) = DJ(\bar{u}, \bar{u}_{\Gamma})(v, v_{\Gamma}) + \frac{1}{2} D^2J(\bar{u}, \bar{u}_{\Gamma})[(v, v_{\Gamma}), (v, v_{\Gamma})] + R_J((u, u_{\Gamma}), (\bar{u}, \bar{u}_{\Gamma})),$$

(3.76)

with the remainder

$$R_J((u, u_{\Gamma}), (\bar{u}, \bar{u}_{\Gamma})) = \int_0^1 (1 - s) \left(D^2J(\bar{u} + sv, \bar{u}_{\Gamma} + sv_{\Gamma}) - D^2J(\bar{u}, \bar{u}_{\Gamma})\right)[(v, v_{\Gamma}), (v, v_{\Gamma})] ds.$$

(3.77)

A lengthy but straightforward calculation, based on the representation formulas (3.67)–(3.69) as well as on the Lipschitz estimates (2.30), (3.6), and (3.39), reveals that

$$\left|R_J((u, u_{\Gamma}), (\bar{u}, \bar{u}_{\Gamma}))\right| \leq C_1 \int_0^1 (1 - s) s \|(v, v_{\Gamma})\|_X^2 ds \leq C_2 \|(v, v_{\Gamma})\|_X \|(v, v_{\Gamma})\|_H^2,$$

(3.78)

with global constants $C_1 > 0$ and $C_2 > 0$ that do not depend on the choice of $(u, u_{\Gamma}) \in U_{ad}$. From this point, we can argue along exactly the same lines as on pages 292–294 in the proof of Theorem 5.17 in [16] to conclude the validity of the assertion.
